The effect of 4-chloro-testosterone acetate, a synthetic derivative of testosterone, combined with prednisone, on 6 patients with hepatic cirrhosis of the Morgagni-Laennec type is described; the patients included 2 women and 4 men who ranged in age from 28 to 74 years. Ten days before the treatment, and until its end, the patients were put on a diet high in proteins and sugar and low in fats and totaling 2,470 calories per day. Prednisone was given by mouth in a dose of 30 mg. per day, divided into 3 subdoses, and 4-chloro-testosterone acetate was given intramuscularly in a dose of 50 mg. per day. With time the prednisone dosage was reduced to 10 mg. per day. Two patients, in very poor condition, died after a slight clinical improvement shown at the beginning of the treatment. The remaining 4 patients derived a noticeable benefit from the treatment; their body weight increased, their strength returned, and their general condition improved. Laboratory tests showed that diuresis had increased, ascites and edema had disappeared, the balance of minerals had become normal, bilirubinemia had decreased, cholesterol level had remained unchanged, and nitrogen had become positive. A tendency toward normal of the electrophoretic curve was observed.

Comparative Experimental Investigations on New Sulfonamides with Diuretic and "Salt-Diuretic" Effect. J. J. Chart, A. A. Renzi, W. Barrett and H. Sheppard. Schweiz. med. Wchnschr. 89:325-331 (March 21) 1959 (In German) [Basel, Switzerland].

The authors survey the different groups of diuretics available today, such as digitalis glycosides, diuretics acting by osmosis, substances that induce acidosis, xanthine diuretics such as caffeine, theobromine, and theophylline, mercurial diuretics, inhibitors of carbonic anhydrase, and others. The discovery of chlorothiazide represented a great advance in the field of diuretics. Its natruretic effect is as great as that of orally administered mercurial diuretics, and, in addition, it increases the elimination of chloride, potassium, and bicarbonate. The discovery of the diuretic effect of chlorothiazide and the well-known antibacterial and antidiabetic effects of related substances demonstrated the wide functional spectrum of the sulfonamides. In the course of chemical and pharmaceutical studies in their laboratory, the authors discovered new diuretics of high potency.

In studies on about 125 heterocyclic sulfonamides, hydrochlorothiazide was found to be the most potent diuretic. Tests on rats and dogs showed that under certain experimental conditions hydrochlorothiazide was not only up to 21 times as potent as chlorothiazide but its action was also of longer duration. In rats hydrochlorothiazide inhibited the effect of vasopressin, reserpine, syrosingopine (Singoserp), and adrenalectomy on renal function. It also inhibited the sodium-retaining effect of desoxycorticosterone acetate and aldosterone and enhanced the natruretic action of prednisolone. Its diuretic effect could be demonstrated even in dogs with experimental ascites, which is usually refractory to drugs. In addition, hydrochlorothiazide displayed antihypertensive properties in a certain form of experimental hypertension known as "adrenal regeneration hypertension." On the other hand, it had no influence on high blood pressure induced by hydrocortisone. Hydrochlorothiazide had no demonstrable effect on the gastrointestinal tract. The degree of carbonic anhydrase inhibition produced by hydrochlorothiazide in vitro was only about one-ninth that produced by chlorothiazide and, therefore, is not likely to be of any significance in the diuretic action in vivo.

These results in animal experiments were corroborated by clinical results. Not only was the natruretic effect of hydrochlorothiazide found to be 21 times as great as that of chlorothiazide, but it was also found to have hypotensive effects in human subjects. The authors conclude that hydrochlorothiazide is a new diuretic and "salt-diuretic" which is highly effective by mouth and has a low toxicity. It differs qualitatively and quantitatively from all other diuretics known so far, and these differences can be regarded as advantages in its clinical use in the various indications for diuretic drugs.

PATHOLOGY

Hyperthyroid Crisis: Clinical and Pathological Study of Two Cases. J. M. Cervino, A. Navarro, J. Maggiolo and others. An. Fac. med. Montevideo 43:166-176 (Sept.-Dec.) 1958 (In Spanish) [Montevideo, Uruguay].

Two women, 33 and 40 years old, respectively, with diffuse exophthalmic goiter were hospitalized in the Hospital of the University of Montevideo. In both cases the goiter was large and with intense thrill. In the younger patient acute symptoms of hyperthyroidism appeared 3 months before the consultation. The treatment then consisted of Lugol's solution, in daily dosage of 10 drops, which since it did not modify the symptoms was discontinued on hospitalization. An unexpected hyperthyroid crisis developed on the 7th day after admission. It progressed rapidly, with mental confusion, violent tachycardia, fever, vomiting, and dyspnea complicated by a genital hemorrhage and bilateral pneumonia. The symptoms did not respond to treatment, consisting of sedatives, iodine, cortisone, and the parenteral administration of liquids, and the patient died 6 days after commencement of the crisis. In the older patient hyperthyroidism had lasted for a year and a half. Early in the course of the disease the patient was treated with radioiodine (I^{131}) in a total dosage of 10,000 μc. As a result of this treatment the symptoms were nearly under control, but the size of the goiter was not modified. On admission, the patient was given Lugol's solution, in daily dosage of 15 drops, as preoperative treatment for a thyroidectomy. *During the first 20 days of this treatment* she lost 10 kg. (22 lb.) in weight. A hyperthyroid crisis developed on the 20th day, with vomiting, diarrhea, fever, anxiety, and general diffuse pruritus. The symptoms did not respond to treatment with cortisone and other medicaments used in the first case, and the patient died 12 days after the crisis started.

In both patients the hyperthyroid crisis appeared suddenly and without any apparent cause. Fever was high, but the patients did not perspire. Findings on autopsy consisted of thymolymphatic hyperplasia in one patient and subinvolution of the thymus in the other. Degeneration of the liver and atrophy of the suprarenal cortex were found in both patients. The authors believe that there is a *relationship between the hyperthyroid crisis* exhibited by the patients and the thymic, hepatic, and suprarenal lesions found at autopsy. Discontinuation of iodine treatment in the course of thyrotoxicosis in one patient and administration of the drug to the other after subsidence of the symptoms may have acted as causal factors in rapid aggravation of the visceral lesions which resulted in development of the hyperthyroid crisis.

Chordoma. E. Mauritzen, P. M. Christiansen and F. Zachariae. Nord. med. 61:368-371 (Feb. 26) 1959 (In Danish) [Stockholm].

Chordoma is a rare, histologically well-characterized tumor which occurs along the axial skeleton, most often at the base of the cranium and in the sacral region, growing slowly, expansively, and invasively. Cranial chordomas usually appear at the age of 30 to 40, and sacral chordomas at the age of 50 to 60, but the tumors may occur at any age and are twice as frequent in men as in women. The cause is unknown; etiological significance has been ascribed to trauma. The tendency to metastasis is slight. Subjectively and objectively, the cranial forms give the same symptoms as other intracranial tumors with the same localization. In the vertebral tumors the first and most frequent symptom is backache; later there are motor and sensory disturbances due to pressure on the nerve roots and medulla. The initial symptom in the sacral tumors is most often vague and intermittent pain in the anal region; in the final stages the pain may be more violent and almost intractable. The chordoma shows all transitions, from torpid to fulminant course, and the degree of malignancy can apparently not be judged on the basis of the histological picture. By its growth the tumor causes bone destruction, seen roentgenologically as clarifications with sharp contours. In the cranium ventriculography and in the spinal column myelography can often reveal the tumor. The sacral tumors can sometimes be recognized only on rectal exploration when they are small and presacral.

Preoperative diagnosis of chordoma depends on histological examination. Biopsy, best by aspiration, can be undertaken only with tumors in the sacral region or in the nasopharynx. Macroscopically the tumor is rounded or lobulated, voluminous, firm, and grayish white. On cross section, it is seen to be gelatinous, semitransparent, sometimes containing cysts with mucoid substance. Hemorrhages and necrosis in the tumor are common. The microscopic picture is typical. Treatment is surgical. Radical excision is practically never feasible in cases with sphenoccipital localization. In the sacral cases laminectomy should be performed with resection as high as possible; sacral nerves II and at all events one sacral nerve I must be left. The intervention must be attempted even with small tumors. Recurrence in the course of months and death in the course of years are the rule. On recurrence, excision must be repeated; cases with repeated excisions through a period of years are not uncommon. Where extirpation is impossible, roentgen-ray treatment may lessen, sometimes stop, the pain for a time. Usually patients do not seek medical aid until 2 or 3 years after the first symptoms appear. Two cases of cranial and 3 of sacral chordoma are described.

Involvement of the Liver in the Course of Diseases of the Kidney. A. Vercellone, P. F. Angelino, I. Oddone and F. Linari. Minerva med. 50:475-482 (Feb. 17) 1959 (In Italian) [Turin, Italy].

The pathological involvement of the liver during the progressive stage of certain diseases of the kidney was studied in 58 patients who were free from a primary disorder of the liver. Acute or subacute glomerulonephritis was present in 11 patients, chronic glomerulonephritis in 25, polycystic kidney in 3, kidney disease of urologic origin in 11, and acute anuric tubular disease in 8. Enlarged liver was found in 38 instances (66%); the single hepatic flocculation test was positive for involvement of the liver in 22 patients (55%), and the multiple hepatic flocculation test was positive in 18 (31%). Alteration of the protein composition, being limited to albumin and globulins only, was observed in 28 of the 50 examined patients (56%); alteration of the prothrombin time was observed in 8 of the 23 examined patients (28%). Bilirubinemia values were found to be normal in all instances.

The incidence of enlarged liver was high and uniformly distributed among all patients regardless of the severity of the kidney's lesion. Hepatic flocculation tests revealed involvement of the liver at a higher degree among patients with acute glomerulonephritis than among those with other kidney diseases; these tests also had a prognostic value in the sense of reflecting the progressive course of the disease rather than the extent of the produced damage. Alteration in the flocculation tests was observed in less degree among patients with chronic glomerulonephritis. Protein composition was altered to almost the same extent, as the result of flocculation tests, in patients with acute glomerulonephritis, and to a greater extent in those with chronic glomerulonephritis. The anatomico-pathological [illegible] and functional findings was limited to the few instances in which autopsy was performed; there seemed to be revealed a higher incidence of liver involvement than the clinical and functional examinations indicated. This investigation has thus suggested the pathological involvement of the liver in patients with certain diseases of the kidney.

PHYSIOLOGY

The Use of Methionine, Pyridoxine and Unsaturated Fatty Acids in Coronary Atherosclerosis. P. E. Lukomsky. Sovet. med. 23:14-21 (no. 3) 1959 (In Russian) [Moscow].

The author studied the action of methionine, pyridoxine, and unsaturated fatty acids on the indexes of lipid and protein exchange in patients with coronary atherosclerosis. Methionine was employed in a daily dose of 6 Gm. for 20 days. The dosage of pyridoxine was 50 to 100 mg. daily for 10 to 20 days. Unsaturated fatty acids were used in a mixture with ethyl ethers of linoleic and linolenic acids (20 ml. a day for 20 days). Administration of the above agents produced in the majority of patients a reduction in the blood cholesterol level, a rise in the lecithin content, an increase in the lecithin cholesterol correlation, and a drop in the beta-lipoprotein fraction. The total quantity of blood proteins did not undergo any noticeable change. The albumin content increased slightly, while the globulin fractions decreased.

BOOK REVIEWS

The Physician and Group Practice. Edited by Edwin P. Jordan, M.D. Cloth. $6.75. Pp. 238. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1958.

Since World War II group practice has become a subject of widespread interest and discussion. Despite this, there have been few really useful publications on the subject. This book fills the void. It is biased in favor of groups, but that is what is intended and this enhances its value. In spite of this bias, arguments for and against groups are ably brought out. Starting with a brief, but pertinent, historical chapter, the reader is led through a series of interesting and useful discussions of practically all of the topics concerning group practice. The various forms of group structure are discussed and evaluated in a meaningful way. How to start a group and whether to join one are questions that are explored in a helpful manner. Problems encountered in groups, benefits gained from them, steps to take in solving problems, and methods of working through difficulties encountered are all explored and discussed from experience.

The chapters directed to the physician contemplating joining a group are especially good. Guides for evaluating one's own personality and how it might fit into a group practice are presented. Certain points are made about how a group works, about interrelationships of members in a group, and personal satisfaction which can be gained through group practice that could help crystallize one's thoughts in favor of group practice. The constant source of stimulation and education that can be derived through association with colleagues in an informal and formal manner in a group clinic may appeal to many physicians. On the other hand, certain drawbacks should be carefully considered. The chance to advance one's income in an outstanding way is seldom found in a group clinic since income distribution is rarely contingent on bookings alone. Also the opportunity to forge ahead and fulfill a strong desire for personal recognition is not as readily available as in private practice. A group situation is not the best one for a "rugged individual," a man who thrives on competition, or one who wishes to be self-employed. Of necessity, a certain amount of cooperation and harmony must be achieved to promote a successful clinic. These are all factors to be considered and evaluated when contemplating association with a group, and many more are found in this book.

For the group already established there are several chapters which should prove useful. Discussions on internal problems encountered and various solutions to these problems are described. Income distribution is discussed, and suggestions as to effective ways of solving this problem are pointed out. The business side of the clinic is dealt with in detail. These discussions are all by men who are well qualified in their respective fields. Nonessentials have been eliminated and the discussions are brief and to the point. The book is well written and the style is conducive to easy reading. From the first chapter, in which a brief history is found, to the last chapter, which covers the relationship of the clinic and the individual staff member to the community, the reader finds a comprehensive discussion and helpful suggestions.

Treatment of Cancer and Allied Diseases. Volume III: Tumors of the Head and Neck. By seventy authors. Edited by George T. Pack, M.D., F.A.C.S., and Irving M. Ariel, M.D., F.A.C.S. Second edition. Cloth. $30. Pp. 781, with 1028 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1959.

The authors of this volume, which is part of a series of nine volumes now going into its second edition, hail chiefly from the United States and Canada, but include a number from other centers throughout the world. Most of the names are widely known and respected by those interested in this field.

This volume consists of seven sections divided into 52 chapters. It would be difficult to praise it too highly. Elegantly prepared, lavishly and beautifully illustrated, it is what it claims to be, an authoritative statement of today's treatment of tumors of the head and neck. It should be useful for a long time to come.

Burns: Pathology and Therapeutic Applications. By Simon Sevitt, M.D., M.Sc., M.A. Cloth. $7.50, 37s. 6d. Pp. 364, with 85 illustrations. Butterworth & Co. (Publishers) Ltd., 88 Kingsway, London, W. C. 2, England; 1367 Danforth Ave., Toronto 6, Canada, 1957.

In this volume the author deals primarily with the clinical pathology of burns and, where possible, correlates in a most comprehensive manner the interrelationship of physiological derangements, the clinical findings, and therapy. Major emphasis is placed on organs and systems consistently involved in pathological processes secondary to burns. The bibliography is chosen with care to include only reports that have a definite impact on the subject. The illustrations and charts are excellent and ade-

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

quately explained. The mortality of severe burns has not improved in the past 10 years. Attempts to favorably alter statistics have been confined in the most part to improvement or, at least, change in therapy. For the first time an author has approached the impasse by reviewing known pathological changes and their possible cause. This book is an outstanding contribution to medical literature and should be of tremendous value to all physicians interested in the proper management of burns.

A Manual of Anæsthetic Techniques. By William J. Pryor, M.D., Ch.B., F.F.A. With foreword by the late J. H. T. Challis, M.R.C.S., L.R.C.P., F.F.A. Second edition. Cloth. $7. Pp. 228, with 75 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; John Wright & Sons, Ltd., 42-44 Triangle West, Bristol 8, England, 1959.

A number of changes in this primer have resulted in a more modern textbook, although the first edition was written only four years ago. The chapters and content remain essentially the same, except for the inclusion of new agents.

This book is intended primarily for British schools of anesthesia, and for "house" surgeons and "registrars" commencing the practice of anesthesia. Yet it is written so concisely that it lends itself to easy reading by students of medicine, interns, residents, and nurses. The organization of the book is excellent, touching on all the basic problems of anesthesia. There are good photographs and line drawings which are correctly used. The printing and general layout are excellent. The content is somewhat superficial and, while this is, of course, good for the novice, it is of disadvantage to those further along in their training. The book could be improved by amplifying the bibliographies. It can be recommended to nurses, interns, and residents who wish to read a simple and concise presentation of British views on anesthesia.

Pulmonary Circulation: An International Symposium, 1958, Sponsored by the Chicago Heart Association. Edited by Wright R. Adams, M.D., and Ilza Veith, Ph.D. [Impetus and financial assistance for symposium provided by Chicago Heart Association. National Heart Institute, National Institutes of Health, U. S. Public Health Service, contributed to cost of publication by means of grant no. H-3927.] Cloth. $4.50. Pp. 316, with illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 15/16 Queen St., Mayfair, London, W. 1, England, 1959.

This is a record of the proceedings of an international group of physiologists, pathologists, and clinicians gathered to consider the pulmonary circulation in health and disease. It consists of a series of carefully written papers, illustrated with photographs and diagrams and accompanied by a transcript of the ensuing viva-voce discussion. An interesting introductory chapter sketches the history of the pulmonary circulation, especially the remarkably explicit statements on the subject by Michael Servetus in the years before his tragic death in 1553. Six chapters deal with the physiology of the pulmonary circulation and emphasize the complexity of the factors that determine the pressures, rates of flow, and distribution of blood in the lungs. Six chapters on pathology deal especially with the relation of the pulmonary to the bronchial vascular systems and the significance of pulmonary and systemic hypertension. Five chapters on pulmonary circulation in primary disease of the lungs include discussions of the circulatory disturbances in tuberculosis and emphysema. The two last sections consist of seven and six chapters on the pulmonary circulation in congenital and in acquired heart disease respectively.

This book contains much of fundamental importance, if not of immediate practical value, to the physician. Reading is made unnecessarily difficult by occasional oversights. For example, the conscientious student will be puzzled by the confusion of Aryanism with Arianism on page 3 and by the redundant symbols in the mathematics on pages 26 and 63. The reader who picks up the book after an interruption may be baffled by abbreviations like C. C. P. and T. M. P. If he traces them back to where they are first used he may or may not find them expanded. This loss of time could be prevented by appropriate entries in the index, which is otherwise excellent. The book as whole is attractive and inspiring.

Peripheral Vascular Diseases: An Objective Approach. By Travis Winsor, M.D., F.A.C.P., Assistant Clinical Professor of Medicine, University of Southern California School of Medicine, Los Angeles. With foreword by Burrell O. Raulston, M.D. Cloth. $16.50. Pp. 845, with 435 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, Canada, 1959.

It is obvious on reading this book that the author is a well-seasoned, experienced medical teacher. Great pains have been taken to make a difficult subject interesting and easy to understand. There are over 400 illustrations to supplement a well-written, concise textbook. The presentation of material is well planned. After sections on the anatomy and physiology of the circulation of the arms and legs, several chapters are devoted to the techniques that are employed as diagnostic aids. Two chapters show exactly what points are to be covered in taking a patient's case history and in making a physical examination. After a classification of peripheral vascular diseases, each disease is taken up in detail, following the same order of age, sex, race, etiology, history, physical examination, laboratory studies, diagnosis, differential diagnosis, and treatment. Selected references are listed at the end of each chapter.

This is one of the most clearly written as well as comprehensive textbooks on peripheral vascular diseases published in many years. It can be read with pleasure as well as profit by any physician who treats patients with peripheral vascular disease and should be particularly valuable to students and medical residents.

"Allergic" Encephalomyelitis. Proceedings of a Symposium: Experimental "Allergic" Encephalomyelitis and Its Relation to Other Diseases of Man and Animals. Edited by Marian W. Kies, Ph.D., Chief, Section on Biochemistry, Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, Maryland, and Ellsworth C. Alvord, Jr., M.D., Associate Professor of Neurology and Pathology, Baylor University College of Medicine, Houston. Cloth. $13.50. Pp. 576, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1959.

The concept that allergic inflammation of organs may be the result of intrinsic causes in addition to those of extrinsic origin (pollen, molds, dust, foods, drugs, etc.) has attracted serious investigators, particularly in recent years. This concept presumes that the organism can produce antibodies to one of its own organs or tissues, probably as a result of some previous damage to that organ, such as by infection, drugs, or trauma. It is presumed further that such an antibody then reacts with the specific antigen in the healthy organ, producing an allergic inflammation. Such a mechanism has been demonstrated clinically, notably in certain hematological conditions and eye inflammations, and experimentally in a number of organs, such as testes, adrenals, thyroid, and kidneys, formed blood elements, and the nervous system.

Such a concept, which might possibly explain various types of encephalomyelitis and other demyelinating diseases, has received attention experimentally from a large group of investigators. The symposium recorded in this volume represents an exchange of their ideas and experience by 60 significant contributors to this field. The usual method of producing "allergic" encephalomyelitis is by the injection of brain homogenates with Freund's adjuvant. The symposium takes up the subject from three major aspects: (1) clinical and pathological correlations of human and experimental encephalomyelitis, (2) attempts to identify the substance in nervous tissue responsible for the antigenic effect, and (3) immunological aspects, dealing with circulating antibodies, passive transfer, delayed hypersensitivity, and immune tolerance phenomena.

This volume constitutes the essence of experience and thinking on an important segment of autosensitization. It is an up-to-date reference book on a subject which should be of particular interest to immunologists, pathologists, neurologists, specialists in infectious diseases, allergists, and all physicians who are visionary enough to realize that auto-sensitization may prove to be one of the most important factors in the etiology of human disease.

Fundamentals of Otolaryngology: A Textbook of Ear, Nose and Throat Diseases. By Lawrence R. Boies, M.D., Professor of Otolaryngology, Chairman, Department of Otolaryngology, University of Minnesota Medical School, Minneapolis. Associates: Anderson C. Hilding, M.D., and others. Third edition. Cloth. $8. Pp. 510, with 212 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

The authors of this textbook call it a guide for medical students and nonspecialist practitioners. It is safe to say that those more advanced, namely at the residency level and even in the early years of practice, will find much in it that is useful. To the clarity and conciseness of the text is added a profusion of illustrations, for the most part original, and all interesting and well selected. Preceding the discussions on things clinical are sections on applied anatomy and physiology, which are very well done and could grace a larger reference textbook.

It is not easy in an era of rapid change like ours to eliminate outmoded pictures of pathological states and obsolete therapeutic measures. The authors have, however, fully recognized the impact of antibiotics and other agents on altering the appearance, course, and treatment of suppurative conditions, among others, which once were such an important part of disease in otolaryngology. The surgical attacks on deafness, and our present-day handling of carcinoma in this region are likewise adequately discussed. Each chapter ends with an up-to-date list of references to the literature.

Medical Department, United States Army. Surgery in World War II: Hand Surgery. Edited by Sterling Bunnell, M.D. [Prepared under direction of Major General George E. Armstrong, Surgeon General, United States Army.] Colonel John Boyd Coates, Jr., editor in chief. Prepared by Historical Unit, Army Medical Service, under direction of Colonel Calvin H. Goddard. Associate editor for hand surgery: Mary E. McDonald; assistant editor: Janie W. Williams. Office of Surgeon General, Department of Army, Washington 25, D. C. Cloth. $3.75. Pp. 447, with 224 illustrations. Superintendent of Documents, Govern. Print. Off., Washington 25, D. C., 1955.

The importance of hand wounds was not properly recognized until after World War I. As a result of the increased interest in such cases between the two world wars, a number of special centers for the treatment of these injuries were established in World War II both in the United States and overseas. Many of the techniques devised, especially for tendon repair and restoration of lost members or functions, were highly successful. In addition to treatment, many ingenious prosthetic appliances were developed for these patients. The editor of this volume was civilian consultant for hand surgery to the Secretary of War. Such outstanding surgeons as C. W. Cutler Jr., Sterling Bunnell, H. S. Allen, and Mather Cleveland contributed chapters. The book is well written and printed on paper of a high quality. It is illustrated with photographs and line drawings. There is an index.

QUESTIONS AND ANSWERS

PAINFUL HAND

To the Editor:—*A 50-year-old woman complains of severe, boring pain over the dorsum of the right hand and extending to the dorsum of the fingers. This has been present for several years. Initially there was also elbow involvement. There were periodic recurrences, with improvement after several days, and it was years before she consulted a physician. A year and a half ago, the pain in the hand became quite marked, and there has been little improvement since. The pain comes only at night, starting 15 minutes after the patient goes to bed. Relief comes in one or two hours if she sits up in a chair. Normal motor and reflex functions of the right fingers, forearm, and arm are present. The patient is in good health otherwise. Complete examination by a neurologist on three separate occasions has revealed normal findings except for questionable, mild, altered appreciation of light touch and pin prick over the dorsum of the hand. No trophic changes have been noted. Cervical spine x-rays have been normal on several occasions, as have findings on chest x-rays, routine hematological indexes, and special x-rays of the apices of the lungs.*

Homer B. Martin, M.D., Louisville, Ky.

Answer.—The symptom of pain in the arm and hand that occurs when the patient lies down and is relieved when she sits up makes one think of some type of pathological involvement of the brachial plexus, subclavian artery, and thoracic outlet. The information given seems to indicate that a diagnosis of supernumerary rib has been ruled out. One must think first of a condition in which paresthesias and pain develop in the hands and arms because of compression of the subclavian artery and vein and the brachial plexus beneath the coracoid process of the scapula and stretched pectoralis muscle, the so-called subcoracoid-pectoralis minor syndrome. A second condition to be considered is that described by Falconer and Weddell, in which the subclavian artery and the brachial plexus are compressed between the clavicle and first rib by hyperextension of the neck and posterior abduction of the shoulders. In this condition, elevation of the first rib causes narrowing of the space between the first rib and the clavicle with hyperextension of the neck and produces compression of the brachial plexus and subclavian artery. One must also rule out the possibility of an intraspinal lesion, such as spinal cord tumor. These syndromes are more prone to occur in patients of middle age because of loss of tone in the elevator muscles around the shoulder and neck. Heat, massage, and corrective posture exercises for the neck and shoulders, as well as resistance exercises to strengthen the shoulder elevator and retractor muscles, may be given with expectation of some benefit. In addition to this, general posture training should be advised.

ARTERIOSCLEROTIC DISEASE

To the Editor:—*What is the current opinion regarding use of vitamin E and/or lecithin in arteriosclerotic cardiovascular disease? It was my impression it was found ineffective, and therefore abandoned, about 1946 or 1947. Recently several patients have asked about it and say they have heard good claims for it.*

Donald W. Maclean, M.D., Hamilton, Mont.

Answer.—There is little acceptable scientific basis for using vitamin E and/or lecithin in the treatment of arterioscleriotic cardiovascular disease. There are so many possible causes of cardiovascular disease and arteriosclerosis that one cannot say they are directly related to a single vitamin or other substance in the diet or may be prevented by any specific dietary approach. The cause of cardiovascular disease is believed to be related to many factors, including age, sex, heredity, diet, activity, and possibly others.

LATE SYPHILIS AND PENICILLIN SENSITIVITY

To the Editor:—*What is the accepted best treatment for late syphilis in a patient allergic to penicillin?* *C. M. Creswell, M.D., Kenosha, Wis.*

Answer.—It is necessary to evaluate the history of hypersensitivity to penicillin carefully to ascertain its validity and to determine by detailed examination just how important it is to give maximal antisyphilitic therapy. If penicillin sensitivity is verified, such a patient should be given one of the broad-spectrum antibiotics of the tetracycline group, 2 Gm. per day for 10 days to two weeks. At the other extreme, in a patient with taboparesis, for example, with primary optic atrophy, spinal fluid showing elevated cell count and protein level, and unverified history of sensitivity to penicillin, a proper course of action would probably be to start the

Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

patient on steroid therapy and shortly thereafter begin penicillin therapy in adequate dosage, continue to give steroids with a gradual tapering in dosage for a week or two after the penicillin therapy has been completed, and then to watch carefully for possible appearance of allergic reaction; steroid therapy may be reinstituted if necessary.

SEIZURES IN INFANT TWINS

To the Editor:—*Identical twin boys had seizures several hours after their second diphtheria, tetanus, and pertussis immunizations at the age of 6 months. The seizures occurred simultaneously, between the solid and liquid portions of a meal, and were preceded by several minutes of irritability and crying, with no particular provocation. Then rolling back of the eyes and extension and stiffening of the neck and back occurred, followed by clonic movements of the arms, legs, and head. Some pallor, but no cyanosis, was present. The babies were unresponsive during the seizures, which lasted about two minutes and were followed by lethargic consciousness during which they finished their bottles and then slept for two hours. Phenobarbital elixir, 1 teaspoonful twice daily, was given for several days after this and subsequent seizures. The second seizure was also simultaneous in both and occurred two weeks later. Fever has never been present. One twin has had three more essentially similar seizures at the ages of 10 months, 13 months, and 13½ months. The other twin has had no further seizures, but no attempt has been made to detect nocturnal occurrence. Electroencephalograms, done on both at the age of 10½ months, were normal. The twins were born in uneventful multiparous delivery and seem normal in physical and mental development. There is no familial history of epilepsy. Does this seem to be idiopathic epilepsy in spite of the normal electroencephalographic tracings? May these tracings and the apparent failure of one twin to have further seizures be interpreted as favorable prognostic signs, even if idiopathic epilepsy is present? Should the twin who has had additional seizures be continued indefinitely on phenobarbital therapy? Is it advisable at this time to subject one or both to lumbar puncture and blood and x-ray diagnostic studies? There has been no neurological consultation.* *M.D., Illinois.*

Answer.—The occurrence of seizures at the age of 6 months is suggestive of symptomatic rather than idiopathic epilepsy. There is nothing in the description of the individual seizures that would suggest a focal onset. The normal electroencephalograms are not helpful, since this merely means that at the time of sampling no abnormal patterns were present. Since tracings were taken on only one occasion and were normal at that time, further tracings should be obtained. That one twin had two seizures two weeks apart and has had none for the past three and one-half months without medication is a favorable prognostic sign. The other twin, who has had subsequent seizures to a total of five, should certainly have medication continued for at least a year. In view of the complexities of this particular situation, it is definitely advisable to have these children studied carefully by a neurologist and to have a complete laboratory examination. Intracranial as well as metabolic diseases must be considered in these children.

ABSORPTION OF ALKALI

To the Editor:—*Can one use too much alkaline water by drinking and bathing in it? A mineral springs resort caters to people who have such diseases as rheumatism, arthritis, and bursitis, and many seem to show good results. The resort provides hot mineral water, mud baths, and special diets. A number of patients have asked if the body can absorb too much alkaline product.* *Alice S. Cutler, M.D., Los Angeles.*

Answer.—This consultant is unaware of any scientific evidence that use of alkaline water is of benefit to people who have rheumatism, arthritis, and bursitis. It is extremely doubtful that the body could absorb too much so-called alkaline water. A normal, healthy body is well equipped to utilize efficiently the food and water ingested regardless of alkaline or mineral properties. It is probably a good thing that the body has the ability to resist most efforts of the uninformed to tamper with the pH of its fluids. It is not felt that the patients referred to need be concerned over the use of alkaline water in drinking and cooking. No toxic effects are known. There is no evidence that minerals in such waters are absorbed through the intact skin.

CONGENITAL DEFECTS

To the Editor:—*A premature baby weighing 4 lb. (1,814 Gm.) had the following defects: exstrophy of the urinary bladder, prolapse of the ileum, agenesis of the colon, atresia of the anus, lack of fusion of Müller's ducts, absence of external genitalia, lumbar spine bifida, meningocele, club feet, and absence of the lower abdominal wall. In view of the fact that most of these defects occurred in the same region, please specify at what embryonic age and what area was affected.*

M.D., Connecticut.

Answer.—The inhibitions of development described can be ascribed to abnormal conditions in utero toward the end of the fourth week after conception, when the pelvic region is growing especially rapidly. A severe illness of the mother four to six weeks after the last menstrual period might be responsible. Another possible cause is a severe dietary defect. In rats, similar abnormalities have been produced by completely removing folic acid from the mother's diet for a brief period early in pregnancy (Nelson and others, *J. Nutrition* 56:349, 1955).

SALT AND BALDNESS

To the Editor:—*Is there any relationship between the amount of salt ingested in the diet and the development of baldness? There have been newspaper reports of a Scandinavian physician who makes such claims. Also, can the injection of vitamin B_1 prevent mosquito bite?*

Juan Silverio, M.D., Marianao, Cuba.

Answer.—No scientific evidence has been seen that indicates ingestion of salt has any effect on balding. Apparently this is a finding of one Scandinavian physician. No cogent scientific evidence has appeared indicating that thiamine has any mosquito-repelling effect.

DISSEMINATED CHOROIDITIS

To the Editor:—*A patient has choroiditis of unknown cause with numerous scotomas, each corresponding to a white patch in the choroid. His central vision is 20/30 in each eye. The scars on the choroid are not outlined by any pigment. There are no cells in the vitreous and no pigment deposits around the periphery of the patches. It is not known whether any arterioles are constricted, but there have been hemorrhages in the past that have cleared up. There are no opacities except when there are hemorrhages. The peripheral vision is good except for small, fast-moving objects, such as a golf ball in flight. Vision is good except at night and in bright sunlight. It is much better on an overcast or cloudy day. There are no opacities in the lens. His greatest difficulty is photophobia, especially when the sun is low in the sky. His adaptation to dark is poor. He suffered severe sunburns in early youth, and it is questioned whether this could be a factor. This condition has been present at least 15 years. Is there any way to overcome the photophobia, which interferes with driving a car? Is driving permissible under these circumstances? Is there anything besides dark glasses that can be used? Is there any drug that would be of help?*

M.D., New York.

Answer.—The patient apparently has disseminated choroiditis. The retention of good central vision speaks against a congenital disease such as choroideremia or gyrate atrophy. The recurrent hemorrhages also are evidence of an active, acquired process. The "white patch" is probably sclera shining through areas of choroidal atrophy. Since these are old, healed areas, it is unlikely that any form of therapy will change them. Symptomatic aid is also difficult. Night vision is already poor, and, theoretically, dark glasses should not be worn, since all tints reduce the transmission of light. However, one a practical basis, it has been observed that the yellow, so-called shooter's glasses are of aid at dusk in that the contrast of objects against a neutral background is improved. These might be tried here. There may also be an optimal pupil size for this patient, and weak solutions of miotics or mydriatics may be tried.

It is unlikely that severe sunburn in youth is related to the present problem. Intense sunlight may produce a keratoconjunctivitis or a macular lesion (eclipse scotoma) but not a choroiditis. Finally, as long as central vision is 20/30 and the peripheral extent of the visual field is normal, it would seem unfair to proscribe driving an automobile.

VITAMINS IN CANNED FOODS

To the Editor:—*How much loss of vitamins B and C is there in canned and in frozen fruits, vegetables, and fruit juices?*

F. L. Troost, M.D., Holt, Mich.

Answer.—According to the available information, there is little loss of vitamin B complex and vitamin C in the canning of fruits, vegetables, and fruit juices. From the nutritional standpoint, canned or frozen and fresh vegetables are usually considered interchangeable.

LONG-TERM ANTICOAGULANT THERAPY

To the Editor:—*A 54-year-old man is now in the fourth week of his second myocardial infarction. The first occurred eight and one-half years ago. At that time he received no anticoagulants. He made an uneventful recovery and worked as usual until the second infarction. He is making an uneventful recovery and is receiving anticoagulants. He is highly emotional, and now and for some time to come he will be under considerable emotional strain. Should he be given a permanent course of anticoagulant therapy?*

M.D., New Jersey.

Answer.—The subject of long-term anticoagulant therapy is still controversial. It is this consultant's present practice to maintain long-term anticoagulant therapy, where possible, in all patients who have sustained more than one myocardial infarction. This is based on published reports and personal impressions suggesting that the recurrence rate and mortality are reduced by this therapy. This is difficult to prove statistically, but follow-up studies appear to show an improved prognosis in treated as compared to untreated patients. In the case cited, it is recommended that permanent anticoagulant therapy be continued, particularly because of the stresses to which the patient will be exposed. It is assumed that he will cooperate fully in regulation of the anticoagulant dosage by having regular prothrombin time determinations.

MOTH CRYSTAL DERMATITIS

To the Editor:—*Please give information relating to moth crystals (paradichlorobenzene) as a cause of severe dermatitis.* *M.D., Massachusetts.*

Answer.—Paradichlorobenzene occurs in colorless crystals which are used for moth-proofing and other purposes. In undiluted form, it is a strong irritant for human skin. Cases of severe allergic dermatitis due to this substance have been described. The concentration for patch testing to ascertain whether allergic hypersensitivity exists is a 1% solution in alcohol. In addition to the cutaneous reactions produced by paradichlorobenzene, allergic asthma and, after continued exposure to its vapors for years, hepatitis and cataract have been described.

CANCER METASTASES

To the Editor:—*A patient had adenocarcinoma of the kidney a year ago. The kidney was removed, and x-ray treatments were given. Now she has multiple metastases in the abdomen, and she has had another series of x-ray treatments. Are there any favorable reports on use of radioactive gold in similar cases? What other treatment might be given?*

Roy F. Messinger, M.D., Circle, Mont.

Answer.—This consultant knows of no treatment which will offer much in this situation. Nitrogen mustard and thio-tepa, given intraperitoneally if the metastases are small, or intravenously if they are large, might have some palliative value.

ALOPECIA DUE TO PONY TAIL

To the Editor:—*Could wearing the hair in pony-tail style cause alopecia?*

C. W. Jacobson, M.D., Breckenridge, Minn.

Answer.—The pony tail and other forms of hair style resulting in constant traction on the pilary apparatus are capable of producing alopecia. In former years, various marginal types of hair loss were occasionally observed as a result of tight braiding and the use of bobby pins, hair curlers, and similar devices that produced a constant pull on the hair shaft. Recently, a number of instances of marginal hair loss, as well as diffuse central alopecia, have been observed as a result of the constant pull on the hair shaft resulting from the pony tail and similar hair styles.

FAT CONTENT OF SEMEN

To the Editor:—*In answer to the question on coloring of seminal fluid, which appeared in* The Journal, *Dec. 20, 1958, page 2207, the consultant stated that normal semen contains "lecithin, cholesterol, and phosphorized fat." During a discussion with a young married woman on the many facets of "married life," she stated that she enjoys fellatio. It occurred to me that she may be ingesting as much highly concentrated fat each time as would be contained on an untrimmed large steak. This may account for her having trouble losing weight, even though she declares she is watching her diet rigidly. She also has noticed increased development of her breasts. Is there a possible hormonal factor of testosterone or another undiscovered hormone which may be aiding in this reaction and might be helpful to others? Obviously, the imagined or real need for help in this area is costing American women and their husbands millions of dollars each year as well as much emotional turmoil. In Beardwood's chapter on obesity (in Cyclopedia of Medicine, Surgery, Specialties, edited by G. M. Piersol, Philadelphia, F. A. Davis Company, 1958, vol. 9, pp. 813-825), the possibility of the body converting some portion of protein into carbohydrates is stressed. Is there any newer thought along this line? Some people seem to get fat on air alone, or is this the bloating of starvation?*

G. H. Horner, M.D., York, Pa.

Answer.—As far as this consultant is aware, while there may be some psychogenic and genetic factors concerned with obesity, it generally can be ascribed to intake of more calories per day than are expended. No cogent scientific evidence is known indicating that body fat is accumulated in any other way; in order to remove fat it is necessary to ingest fewer calories than one expends. It should be remembered that calories are obtained from protein and carbohydrate as well as from fats. In regard to the possibility of fellatio being a contributing factor in obesity, one would be somewhat skeptical. Even assuming an ejaculation of 10 cc. of semen were all fat, this would be only 90 calories. It is extremely doubtful that this would have a significant effect on inability to take off weight unless, of course, it was practiced several times a day. A useful pamphlet on weight reduction can be obtained for distribution to patients by writing to the Council on Foods and Nutrition, American Medical Association.

International Health Developments . .
Officials Criticize Age Discrimination . .
Officials of Aging Conference . .
Testimony on Insurance Bill . .
HEW Release Policies . .

INTERNATIONAL HEALTH LEGISLATION

Congress was asked to make sure that the proposed international medical research program deals strictly with research efforts and not with medical services.

A pharmaceutical industry official told a House commerce subcommittee that "the implementation of a research effort must be . . . kept administratively and otherwise entirely separate from anything in the nature of a point four [economic assistance] program, however worthy." The witness was Francis Boyer, chairman of the board of Smith Kline & French Laboratories.

The subcommittee, headed by Rep. Kenneth Roberts (D., Ala.), is considering a Senate-passed bill that would set up a new National Institutes of Health for international medical research activities that would be financed by a 50-million-dollar annual authorization.

Boyer also recommended that foreign nations put up matching funds "to lessen any tendency . . . on the one hand to feel that they might as well get on board Uncle Sam's gravy train, or at the other extreme actually to resent what they might call American control of their research with a real and fancied dislocation of their academic salary structure."

Precautions should be taken that United States funds are not used to subsidize the product development of foreign commercial houses, and "grants or contracts under the bill should be confined to academic and other nonprofit centers and individuals," said Mr. Boyer.

The program should proceed slowly and on a small scale at first, he said, partly because of the desirability of balancing the budget and partly because of "some apprehensions as to our supply of medical manpower."

The American Medical Association supports the legislation and has also said the emphasis should be on research, not services, as the measure states.

In another development President Eisenhower expressed some misgivings about another international program with medical implications—the so-called great white fleet plan to send reserve Navy hospital and other ships abroad to aid nations hit by epidemics and other disasters. The chief executive said he is "always suspicious of helpful plans" that originate solely with the donating nation. Under the foreign aid program, he noted, countries needing and desiring help draw up their own plans and suggestions as to how the United States might assist them.

Meanwhile, the foreign aid authorization bill signed by the President contained a provision authorizing at the chief executive's discretion the spending of 2 million dollars for research into possibilities of eradication of diseases.

And a Senate government operations subcommittee issued a report, "Cancer: A Worldwide Menace," that stated, in part, "The evidence is clear that cancer is a world problem, best solved by research on a world basis."

AGE DISCRIMINATION IN EMPLOYMENT CRITICIZED

Federal officials told Congress that mandatory retirement ages and age discrimination in employment are two major problems that need to be solved to help elderly persons lead more useful lives.

Testifying before the special Senate subcommittee studying problems of the aged, witnesses from the Labor Department and the Civil Service Commission said that arbitrary industry standards on employees' ages add to the problems of the elderly.

O. Glenn Stahl, director of the Civil Service Commission's Bureau of Programs and Standards, said the government is setting an example for private industry by employing workers "without regard to age." He said that persons over 70 years of age often continue to work for the government, if they wish. There is no mandatory retirement age in government, he pointed out, adding that private industry might well follow suit.

Newell Brown, Assistant Secretary of Labor, said that one of the department's chief goals is to promote public understanding of the fact that there is no fixed age at which a person becomes too old to work and that each worker should be considered for employment on the basis of his individual qualifications as these measure up to the basic requirements of the job.

The general objective of the department's older worker program, he said, "is to help make it possible for older persons who desire and are able to work to continue their productive lives through suitable gainful employment."

Another witness before the subcommittee, Sen. Jacob K. Javits (R., N. Y.), said that discrimination against older workers "deprives the nation of a most important resource of experienced, often highly skilled employees, adds materially to the number of persons requiring public assistance, and deprives mature citizens of the dignity and status of self-support and continued participation in constructive economic activity."

Sen. Pat McNamara (D., Mich.), subcommittee chairman, remarked that "this barrier of age discrimination" is one of the chief issues before the subcommittee. He asked the witnesses whether the employment of older persons would reduce job

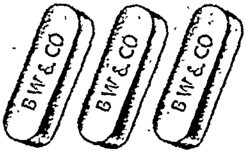
Tuckahoe, N. Y.

'CARDILATE'



opportunities for younger persons. They said that there should be plenty of jobs for all in an expanding economy.

The subcommittee plans to hold hearings in at least six cities during the fall to hear local officials and representatives of interested organizations testify on problems in their areas.

CHAIRMEN NAMED FOR AGING CONFERENCE COMMITTEES

The chairmen of the 20 planning committees for the 1961 White House Conference on the Aging were appointed by Robert W. Kean, chairman of the advisory committee to the conference. The chairmen, all members of the 130-member advisory committee, met for an all-day session in Washington on July 30 to speed preparations for the conference.

"The planning committees have been established to cover the areas of major interests to the nation's increasing older population," said Kean.

Those named chairmen included Dr. Leonard W. Larson, Chairman of the American Medical Association's Board of Trustees, committee on health and medical care; Dr. Howard A. Rusk, Bellevue Medical Center, committee on rehabilitation; Dr. Ewald W. Bussey, Durham, N. C., committee on research in gerontology; Charles I. Schottland, former social security commissioner, committee on income maintenance and implications of inflation and other economic factors; the very Rev. Msgr. Raymond J. Gallagher, rabbi Marc H. Tannenbaum, and the Rev. William J. Villaume, co-chairmen, committee on religion; John B. Martin Jr., committee on population trends and social and economic implications; G. Warfield Hobbs, committee on impact of inflation on retired citizens; Dwight S. Sargent, committee on employment security and retirement; Joseph P. Anderson, committee on social service; Walter C. Nelson, committee on housing; George E. Davis, committee on education; Wilma Donahue, committee on role and training of professional personnel; Margaret A. Ireland, committee on family life, family relationships, and friends; Joseph Prendergast, committee on free time, recreation, voluntary services, and citizenship participation; Hardin B. Jones, committee on research in gerontology (biological); John E. Anderson, committee on research in gerontology (social science); Robert MacRae, committee on local community organization; Brevard Crihfield, committee on state organization; Viola Hymes, committee on national voluntary services and service organizations; and Harry G. Haskell Jr., committee on federal organizations and programs.

BLUE CROSS, BLUE SHIELD SUPPORT HEALTH INSURANCE BILL

Spokesman for the Blue Cross Association and Blue Shield Medical Care Plans asked Congress to approve a "long overdue" program of voluntary health insurance for civilian federal workers.

Testifying before the House Post Office and Civil Service Committee they endorsed, with minor changes, the legislation that cleared the Senate earlier this session.

"The nation's largest employer should aid its employees in securing needed health services," declared J. Douglas Colman, vice-president and secretary of Blue Cross. "The United States is the only large industrial nation in which personal health services are not a major governmental responsibility," he said, noting that "contributions to the cost of health service benefits is increasingly a standard part of the benefits offered by private employers with whom the federal government competes for competent personnel."

Dr. Donald Stubbs, chairman of the board of the national association of Blue Shield medical care plans, said health insurance "has become a condition of employment for a large segment of the population and in this respect the government has fallen behind the times by not helping to provide for the better health care of its employees."

Both officials recommended clarifying a section of the measure that authorizes the Civil Service Commission to approve, among other plans, "one governmentwide service benefit plan. . . ." Colman said that this might be interpreted as a requirement "to negotiate service contracts with physicians and hospitals in every city throughout the world where even one federal employee is located."

The American Medical Association, which also supports the bill, raised a similar objection to this provision.

The measure calls for the government to pay half the cost of the insurance, and gives the Civil Service Commission wide flexibility in establishing terms for the insurance. It would cost the government about 150 million dollars a year.

FLEMMING DEFENDS RELEASE POLICY

Arthur S. Flemming, Secretary of Health, Education, and Welfare, [illegible] a published charge that the department is misrepresenting government medical research achievements.

He said announcements should be made first in scientific journals, although in some important cases the department "has the responsibility" of simultaneously transmitting the information to the lay public.

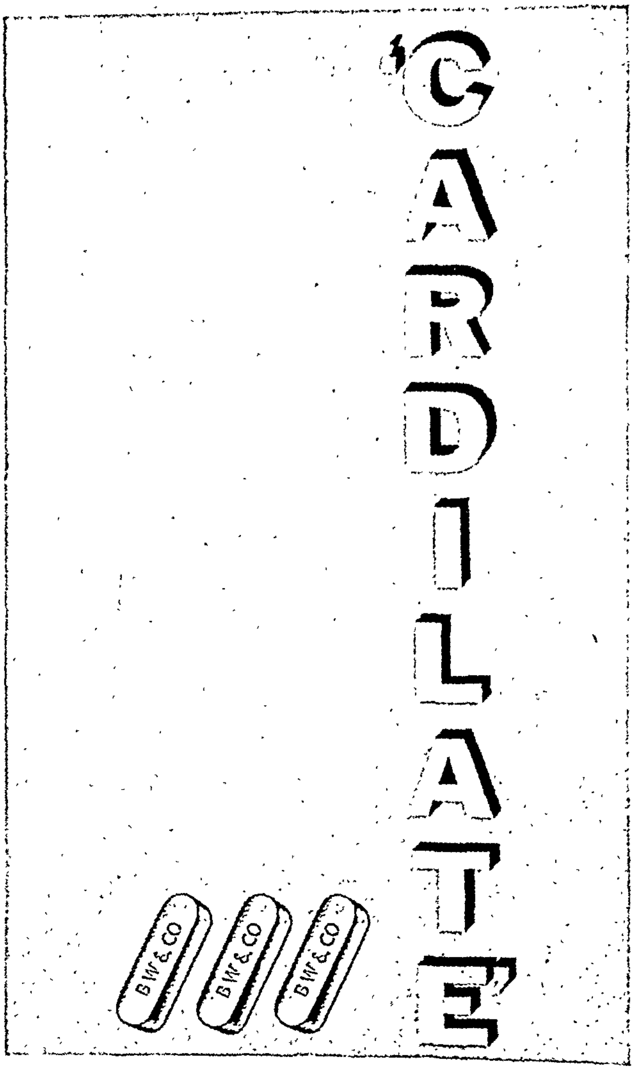
Flemming conceded that in one case the first sentence of a press release was "inadequate, in that it failed to indicate the extensive research, by both National Institutes of Health scientists and others, which, starting more than a decade ago, led to the results described in the release."

The first sentence of the release said, "Scientists at the National Institute of Mental Health have discovered the answers to one form of severe mental illness." The illness was phenylpyruvic oligophrenia.

Another disputed release started "Surgeon General Leroy E. Burney . . . announced today that a 'happy accident' of medical research has led to the discovery of a powerful new drug for treatment of gout. . . ."

Flemming said the release did not claim credit for NIH, and provided "full identification of the scientists, both in and out of government, and mentioned the institutions with which they were associated."

Asked at a news conference whether there might be any "political purpose" in the timing of news releases, often months after publication in scientific papers, Mr. Flemming said this was "certainly" not true. He said that he releases statements only when branches of HEW recommend that he do so.



'CARDILATE'
sublingual
tablets for
angina pectoris

Sublingual administration obviates inactivation of nitrites in gastrointestinal tract.

Most closely approximates nitroglycerin in frequency and degree of effectiveness.

PSYCHOSOMATIC PROBLEMS IN A RAPIDLY GROWING SUBURB

Richard E. Gordon, M.D.
and
Katherine K. Gordon, B.S., Englewood, N. J.

Certain diseases were compared as to their incidence among patients admitted to general hospitals in three communities which differed markedly as to their rate of growth in recent years and as to the mobility of their inhabitants. Bronchopneumonia, representing disorders not psychosomatic in origin, was compared with duodenal ulcer and cardiovascular disease, representing tension disorders, and with asthma, considered as a parasympathetic psychosomatic disorder. In addition it was possible to compare figures obtained in 1958 with figures obtained in 1950. Asthma was more prevalent in the community with the highest percentage of older people. The tension disorders were most prevalent in the most rapidly growing suburban community. This finding agreed with results of previous studies of the distribution of emotional disorders among different groups within the communities.

MULTIPLE interrelated factors have been reported to be associated with psychosomatic disorders—genetic predisposition, body type and constitutional variables, early psychological conditioning, climate, diet, personality, occupation, exercise, and others. Recently, particularly in patients with coronary heart disease, important findings have been reported relating definite somatic abnormalities to behavior patterns and socioeconomic pressures and stresses.

Lee and Schneider[1] recently showed that lesser executives and white-collar workers were more prone to hypertension and arteriosclerosis than top executives. Friedman and Rosenman[2] reported their important findings that men exhibiting a behavior pattern primarily characterized by intense ambition, competitive "drive," preoccupation with "deadlines," and a sense of time urgency were more likely candidates for coronary artery disease than comparable groups of either more lackadaisical or chronically anxious and insecure, but noncompetitive, persons. American society praises and highly rewards competitive, "getting ahead" behavior. Such persons by their energy and drive, by working long hours, and by going to college at night often rise from working class, immigrant origins into the American middle class, buy their own homes, and move into the rapidly growing suburbs.

It would be interesting to learn whether incidences of coronary heart disease as well as several other psychosomatic disorders are rising in expand-

From Columbia University, New York, and the Mental Health Research Unit, Englewood Hospital.

ing suburban communities. For the rapidly changing community itself, with its higher taxes and overloaded schools, roads, recreational facilities, and other resources, may contribute its share of stress to a patient's overburdened psychophysiological functioning. Futhermore, this suburban move uproots all the family and places strains on the housewife[3] and her sons particularly that apparently interfere with their emotional health.

TABLE 1.—*Over-all Percentages of Various Disorders in Adults in Three Community Hospitals, 1956-1958*

	Englewood Hospital*	Kingston Hospital†	Olean General Hospital‡
Asthma	2.1	4.7	2.0
Coronary thrombosis	11.7	3.0	2.0
Essential hypertension	2.3	2.0	1.7
Hypertensive cardiovascular disease	12.0	3.2	5.0
Duodenal ulcer	9.6	7.1	2.8
Bronchopneumonia	7.3	5.3	5.0
Total no. of adult medical admissions	1,452	1,236	2,102

* In a rapidly growing suburb.
† In a moderate-growth community.
‡ In a slow-growth area.

Sociologists and social psychologists have for some time reported on the hazards of high-speed modern life, too rapid social mobility, and too reckless efforts at getting ahead and their relationship to family disorganization, divorce, delinquency, and emotional disorder.[4] Perhaps the rapid suburbanization of much of the American population is associated with attendant psychosomatic as well as emotional difficulties. If so, efforts at management and prevention cannot be directed at the individual patient alone—his personality, physical condition, and diet—but must also have family, industrial, and communitywide public health features.

Procedure of Study

Percentages of total medical admissions for asthma, coronary thrombosis, duodenal ulcer, essential hypertension, and hypertensive cardiovascular disease were obtained from three general hospitals, each in a community of different geographical mobility. The percentage incidence of bronchopneumonia in the three hospitals was used for comparison. The Englewood Hospital in Bergen County, New Jersey, represented a rapidly growing suburb; Kingston Hospital, Ulster County, New York, a moderate-growth, mixed-rural community; and Olean General Hospital, Cattaraugus County, New York, a stable rural area.

The problem was approached by several methods. *A comparison was made of percentages of the disorders* in admissions to all three hospitals in the year 1957. Olean General and Englewood were compared for relative change in gross percentages of these disorders from 1950 to 1958. Kingston and Englewood were compared for age and sex patterning of patients in 1957. Finally, possible change in age and sex patterning in Englewood Hospital during the period 1950-1958 was investigated.

Census data gave growth-rates as an indicant of geographical mobility. Previous studies have shown that rate of geographical mobility is highly correlated with cultural and socioeconomic mobility in Englewood and Bergen counties generally.[34] A sample of records of 97 Englewood Hospital adult patients, all under 60 years of age and admitted for psychosomatic disorders, gave marital status information (95% of men and 92% of women married).

It is hypothesized that differences in incidence of these psychosomatic disorders reflect differences in the social patterns in the communities the hospitals serve. It is assumed that modern diagnostic and therapeutic measures are reasonably constant in the medical practice of the several communities. Similarly, it is assumed that any change in percentages of psychosomatic disorders found in the periods under study is not greatly affected by any change in incidence of other disorders, such as a decrease in bacterial infection due to more effective antibiotics.

Results

Asthma.—For asthma, over-all incidence was lower in Englewood than in Kingston Hospital (x^2 [chi square]=23, $p < 0.001$) but slightly higher than in Olean (table 1). As with every other disorder, however, percentages of young women with asthma (ages 18 to 44) were higher in Englewood than in Kingston, but not significantly so (table 3).

Coronary Thrombosis.—Incidence of coronary thrombosis was much higher in Englewood than in Kingston or Olean hospitals in 1957. The percentage has risen in both rural and suburban hospitals since 1950 (table 2). (Comparing Englewood with Olean Hospital in 1957, x^2=130, $p < 0.001$; Englewood 1950-1952 versus 1953-1958, x^2=10.3, p near 0.001). The incidence of coronary thrombosis in younger men rose, but not significantly, in Englewood from 1950 to 1958 (table 4).

Duodenal Ulcer.—Incidence of duodenal ulcer was again much higher in Englewood than in Kingston, even more so than in Olean (x^2=75, $p < 0.001$ [table 1]). But there has been only a slight increase in over-all incidence in Englewood (table 2), again associated with a rise in number of young women (table 4).

TABLE 2.—*Change in Over-all Percentages of Various Disorders in Englewood and Olean Hospitals, 1950-1958*

	Coronary Thrombosis		Duodenal Ulcer		Essential Hypertension		Hypertensive Cardiovascular Disease		Bronchopneumonia	
	Englewood	Olean	Englewood	Olean	Englewood	Olean	Englewood	Olean	Englewood	Olean
1950-1952	8.5	2.1	4.5	1.7	2.0	1.4	13.5	5.8	5.4	4.8
1953-1955	14.3	2.9	4.5	2.1	3.0	1.1	18.0	4.1	6.1	4.4
1956-1958	12.5	2.7	4.7	1.9	2.4	1.3	12.0	5.0	7.4	5.0

Much higher percentages of women had duodenal ulcer in Englewood than in Kingston Hospital (for all women, x^2=7.9, $p < 0.01$; for young women, x^2=5.8, $p < 0.02$ [table 3]). Since 1950 the incidence of duodenal ulcer in women of all age groups has risen in Englewood ($\chi^2=3.7$, p near 0.05), but particularly that in young women ($\chi^2=4.2$, $p<0.05$).

Essential Hypertension and Hypertensive Cardiovascular Disease.—Englewood's incidence of essential hypertension and hypertensive cardiovascular disease was significantly higher than that of Kingston ($\chi^2=4.7$, $p<0.05$) and very significantly higher than Olean's ($\chi^2=45$, $p<0.001$) (table 1). There was a rise in Englewood in essential hypertension from 1950 to the present ($\chi^2=3.1$, p near 0.05), but not in Olean (table 2). The percentage of young women with hypertension was also greater in Englewood than in Kingston, but not significantly (table 3). A rise in incidence of essential hypertension from 9% to 15% occurred from 1950 to 1958 in Englewood (table 4), but not to statistically significant levels.

Bronchopneumonia.—The over-all percentage of bronchopneumonia in the three community hospitals was not very much different in the year 1957 (table 1) and was relatively unchanged through the years in Olean (table 2). However, two consistent trends appear, for higher percentages in boys and young women patients in Englewood in recent years as compared both to the other hospitals and to previous years in the Englewood Hospital (tables 3 and 4). These differences are statistically significant. (For young men versus young women in Englewood Hospital, comparing 1950-1952 and 1956-1958, $\chi^2=5.4$, $p<0.02$; young men versus young women, Englewood and Kingston hospitals, 1957, $\chi^2=4.0$, $p<0.05$; boys versus girls, Englewood Hospital, 1950-1952 and 1956-1958, $\chi^2=3.4$, p near 0.05; and boys versus girls, Englewood and Kingston hospitals, 1957, $\chi^2=4.7$, $p<0.05$).

Comment

Relationship of Degree of Mobility and Percentage of Psychosomatic Disorders.—It would appear that, except for asthma, there was a direct and very significant relationship between the degree of mobility of the community and the percentages of the several psychosomatic disorders studied. Englewood Hospital, in a fast-growing suburb, had the highest percentages of patients with coronary thrombosis, duodenal ulcer, essential hypertension, and hypertensive cardiovascular disease; Kingston Hospital was intermediate; and Olean General Hospital, in a stable rural community of western New York state, had the lowest incidence (table 1).

It seems that, with the rapid growth of the suburban area around Englewood since 1950, percentages of coronary thrombosis and hypertension have increased more rapidly. In Olean Hospital, in a rural community, only the percentage of coronary thrombosis increased. Interestingly, incidence of bronchopneumonia also increased in Englewood, primarily because of the greater number of boy and young women patients (table 2).

For every disorder in Englewood Hospital percentages of young women patients (between 18 and 44 years of age) exceeded those in Kingston

Hospital, most particularly for hypertension and ulcer. Generally women of all ages were more frequently patients with psychosomatic disorders in Englewood than in Kingston, but this was largely due to the preponderance of the young group in the population. Of these women, 92% were married. Moreover, relative percentages of women patients with coronary thrombosis and duodenal ulcer have increased in Englewood Hospital.

More older persons were patients with every psychosomatic disorder in Kingston than in Englewood Hospital. However, percentage-wise, more older persons in Englewood were patients with bronchopneumonia, the nonpsychosomatic disorder used for comparison. (The greater general incidence of elderly patients with psychosomatic disorders in Kingston Hospital is not surprising, as that community has a larger older population, estimated from the 1950 census as about 1.4 times as many persons past 60 years of age as in the Englewood area.) Comparable mobilities, with migration rates calculated from the 1950 census used as an index and supported by subsequent interim census reports, indicate that the average annual migration rate for Bergen County has been about 7%, for Ulster County about 5%, and for Cattaraugas 4%.

It seemed that rapid social mobility was related not only to emotional difficulties but also to a rising incidence of tension-related psychosomatic disorders. Such disorders as coronary thrombosis, duodenal ulcer, essential hypertension, and hypertensive cardiovascular disease were more prevalent in the rapidly growing mobile communities and less so in the more slow-growing, stable one. The incidence paralleled the degree of mobility. It seems that divorce and suicide rates also follow this pattern, and this is presently under further investigation.

Not only were there differences between more and less mobile communities, but within the same more mobile county the incidence of coronary thrombosis and hypertension rose in the period of rapid community growth and expansion—1950-1958. Incidence of coronary thrombosis also rose in the more stable comparison community, suggesting that we are observing a large-scale problem, more prevalent in, but not limited to, the rapidly growing areas of the country and associated with the national increase in mobility since World War II.

In this study, as well as others, it was apparent that, although all groups presently have more difficulties, the young married women were relatively more prone to react with psychosomatic disorders and other emotional difficulties than other adult groups in the mobile communities. Boys seemed to suffer more than girls. The elderly were having greater difficulties in the rural areas where emigration, rather than immigration, is the main form of geographical mobility.

One cannot assume a causal relationship between mobility and over-all rise in incidence of psychosomatic disorders seen in a suburban hospital, for an argument can be documented that the emotionally unstable are more mobile than the emotionally stable and that the potentially hypertensive or ulcerous will be more mobile. But it is harder to show why married women and sons, whose rates are rising, were more unstable than the men, when much of geographical mobility frequently is related to husbands' new job opportunities. The wives and sons are sometimes reluctant travelers. There is plenty of evidence that the marginally adjusted persons who have constitutional susceptibilities, and who have been sensitized by unfortunate early life experiences, become psychiatric and psychosomatic patients more often. Perhaps this mobility increases the strains on their already heavily taxed systems to the point of illness. Thus there seems to be a circular causal relationship. But in a small percentage of cases there is no history of major predisposition.

One disease, asthma, was more prevalent in the rural community. This illness is not a tension disorder but a parasympathetic psychosomatic disorder, closely associated with emotional depression and "unresolved dependence."[5] It occurred more frequently in Kingston Hospital in the heart of the Hudson Valley, which is noted for respiratory ailments and which is a community with many lonesome elderly people. A high incidence was found in the older members of the population. They are being left behind there, are without adequate activities, and are often quite depressed.

Change in Social Role of Married Women.—Married women are undergoing a long-term change in social role in the United States as a result of greater economic, political, and educational opportunity. This opportunity brings with it expectations for greater independence and assumption of responsibility.

Traditionally, and particularly in the more restrictive ethnic groups, into which many of the Bergen County women were born, women were protected and kept dependent but were provided much help and honor in their homemaking and child-rearing role by the other members of the family. With the disruption of big multigeneration family living and the moving of married women away from their parental homes and neighborhoods, in the present American pattern, many women are exposed to responsibilities for which they are poorly prepared, and for which they receive little assistance, guidance, relief, and relatively less recognition and praise.

They have not learned the techniques of considerate self-assertiveness necessary to making friends, of competition, and of realistic independence. They are shy, unassertive, and insecure. An unrealistic precarious "pseudoindependence" is thrust on them. The other women in the community are often similarly strained, and are often from different religious, ethnic, and cultural backgrounds. Communication and mutual assistance thus do not readily take place. Husbands do not understand the problem either and are themselves working long hours, fulfilling their business responsibilities. They are often chagrined at their wives' complaints but are not very encouraging, respecting, praising, or helpful with "women's work."

Some women, often similarly protected and restricted in early life, have also acquired intellectual, social, business and professional, and artistic interests and tastes as a result of their educations and backgrounds which often go frustrated in the housewife's daily routine. The woman who constitutionally or genetically was endowed with a sensitive stomach, and who may have undergone some early conditioning through unpleasant experiences with food and eating, may develop an ulcer in a continuing atmosphere of anxiety, chronic tension, frustration, and confusion which she cannot comprehend and relieve. She may perhaps be particularly susceptible, if she has acquired the temperament described by Friedman and Rosenman, and drives herself compulsively to maintain a meticulously clean house, meanwhile meeting schedule deadlines—chauffeuring husband to and from the commuter train and children to and from school, preparing meals, and so forth.

Under these circumstances of increased demands and expectations of poorly prepared women, with attendant rise in their rates of situational emotional maladjustments and other psychiatric disorders, and in psychosomatic reactions, are we observing the beginnings of an equalizing of the morbidity rates of the sexes? In the 19th century ulcer was more prevalent in women than in men, as it is at present.[6] Already in Englewood Hospital 40% of ulcer cases in young adults occur in women. Even the incidence of bronchopneumonia is rising with them, for young women without family and friends to rely on, and who cannot afford paid help, cannot go to bed with a bad cold but must care for their preschool children, shop, and continue "on the job" —until they are laid low by pneumonia. It seems apparent that any attempt to relieve the tensions related to psychosomatic disease must take into consideration the needs of wives and children, as well as husbands, all of whom may suffer.

Assumption of and Preparation for Responsibility in Men.—Let us consider further the problem of assumption of and preparation for responsibility with regard to men. Lee and Schneider's[1] very interesting paper on hypertension and arteriosclerosis in executives showed that top executives had less of these disorders than the lesser executives and white-collar workers. This finding is not surprising when we consider some of the sociodynamics and psychodynamics.

Is it responsibility alone that leads to emotional strain? Many top executives have had excellent preparation for responsibility, through upper-middle-class and upper-class birth, good education, and guidance and assistance while they were young by family and friends who themselves were experienced top executives. They do not necessarily feel "the strains of executive responsibility" too severely. The making of decisions does not of necessity provoke anxiety and tension. It is the possibly deleterious consequences to the decision maker of a wrong decision which may cause him anxiety and grief.

The person who has been sensitized by stresses in early life may be far more susceptible to emotional and psychosomatic disorders. He may have come from a home in which his father was out of work during the Depression and took to drink, in which the parents were immigrants and could not prepare him well for adjustment to the American culture, or in which parents were separated, divorced, or widowed. This person, if exposed to the realistic strains of upward mobility, is more likely to develop an emotional and/or psychophysiological disturbance in adult life. He is usually not a top executive; he has not come that far yet. He is struggling upward out of the working class into subexecutive white-collar jobs and lesser managerial positions for a secure, more stimulating, and interesting life, and in order that he will not be thrown back into an often hungry, or stultifying, or degraded position in a culture that recognizes the man who gets ahead and scorns the failure. The recent-generation American, the night school scholar, the man from the minority ethnic or religious group, the struggling rapidly upwardly (and against downwardly) mobile person is more likely to be the potential psychiatric or psychosomatic patient. He usually has no close and loving experienced parent to guide him in his decisions. He must learn everything the hard way—by personal trial and success or error. The upwardly mobile person may have a great deal to lose and knows it well. If his decision backfires he may lose his job and his future and be thrown back to the insecurities of his past. He wears his responsibilities heavily.

The financially and socially well-to-do and well-born person has usually been burned less in his early years and is often well established so that he cannot be much hurt if he makes a bad decision once in a while. He has not much to fear from the past, present, or future so can relax at the end of the day, can exercise, look after his health, and play. Often (but not always) our top executives are born to their class. They carry more responsibility, but they have had better preparation and less to fear and dread. The lesser executives and nonexecutive white-collar groups have usually risen to their positions from humbler origins. Our Englewood and Bergen County new residents, and particularly our psychiatric patients, are largely drawn from the latter groups.[7] One wonders whether physicians, too, who also have a higher mortality from heart disease,[8] are not in large part from similar socioeconomic situations.

The upwardly mobile are often fiercely competitive, "driving," and excitable in their effort to continue to strive upward and to keep from being crushed back down. Their physiological mechanisms for coping with both acute and chronic stress are already overtaxed. They themselves are pushed and they are continually struggling with each other for a place at the top. Hollingshead and Redlich[9] have shown that the top echelon of the upper class insulate themselves from the upwardly striving and make it not at all easy for the latter to rise. They have already arrived and naturally protect themselves from the unpleasant aggressiveness and competitiveness of the climbers struggling upward. Thus the upwardly mobile usually must compete most of the way for greater security and an enjoyable rewarding life. In the mobile suburbs they are the majority. All struggling together, they compete with each other. They provoke discomforts for each other in home, office, and on the highway, and they recondition each other's emotional-psychophysiological disturbances. This type of person will only stop when he feels that he has found a really secure and interesting place for himself and can settle back, feeling well protected, and begin to relax and enjoy living. When the memories of his past are no longer supported by present dangers, his anxiety and tension can subside. However, he still has to learn to play, for most of his education has been for work, not for constructive leisure, and perhaps by this time irreversible anatomic damage already may have occurred to his system.

His wife will relax after she also has learned greater skill, efficiency, and confidence in coping with her new and difficult responsibilities and when she has found helpful assistants, helpers, and advisers among her family and new neighbors and in her husband. She, as well as her husband, once she has the security of fulfilling her responsibilities comfortably, must still learn better to enjoy her freedom, independence, and leisure constructively. The psychophysiological mechanism of reciprocal inhibition will then operate. The person who is enjoying himself does not experience emotional tension symptoms readily.

The Father-Son Problem.—As to the father-son problem, the modern middle-class father's work and leisure are geared toward his individual economic success. His son contributes little to this, in contrast to a farmer's or blacksmith's son. On the contrary, children interfere with personal advancement as well as freedom. The cost of their education represents an increasingly greater threat to the father's financial security. Children interfere with husband and wife companionship and personal leisure. Fathers, sensing their sons' needs, but having little in common that is mutually profitable, may try to play with sons on the latters' level. This is done partly out of a sense of obligation and compulsion and, needless to say, is not as wholesome as if it arose out of larger common goals.[10]

Conspicuous Consumption.—Many of our patients are overconcerned about keeping up appearances: a new car every few years is to them almost a necessity, there cannot be a blade of crabgrass in the lawn, the house must be spotless and dustless, the children must be kept scrubbed clean. For the already overstrained couple, "conspicuous consumption" can help cause bad tempers and high blood pressure.

Effectiveness of Insight in Psychotherapy.—A word of caution: only if a person's difficulties are entirely in the past, and his present is devoid of realistic anxiety-producing and tension-producing dangers, can he "take hold of himself," "slow down," and "stop worrying"—and then not always. He usually must be shown why he is under tension and that the strain is now over. This is the essence of the effectiveness of insight in psychotherapy. Our autonomic nervous system functions as its name indicates—automatically—it is not under conscious control. We cannot will it to "calm down." It reacts reflexly to actual events in our present lives or reminders of stressful events from the past (conditioned stimuli) which indicate possible potential danger. Injunctions to "stop pushing yourself or you'll have a heart attack" may even add a new fearful stress unless practical suggestions are offered as to the means by which life can be made much easier and more realistically secure. A pattern of behavior, both psychological and psychophysiological, can be changed, but only after removal of real objective difficulties—"traumas," "stresses," "strains," psychological or physical injuries—dangers that are both conditioned and unconditioned stimuli for evoking the behavior.

Once the real situation has improved, a calming down can occur. However, a psychosomatic or emotional disorder is itself a stress, and a disgrace in our society's thinking. The fears of patients with psychophysiological symptoms, whether with organic lesions or not, are increased by the very presence of the symptoms. They have seen friends and relatives succumb to emotional disorder, heart attacks, or early death. They are thus prone to dread these consequences. This new worry itself, conditioned to real occurrences in their lives, exacerbates their disorders. Thus personal and social strains in their lives arouse tension, make for fears, and contribute to psychophysiological disorders. Then the symptoms of the disorder add to the fears and a vicious cycle is under way.

Thus we help our patients not by frightening injunctions but by clear explanations of how their symptoms and disorders came about, the physiological mechanisms, personality factors, and social and economic problems. Understanding is reassuring and can lead to intelligent action. Further guidance as to the method of reducing the stresses and strains —the dangers and difficulties in their lives—may permit a calming down and gradual extinction of the reversible part of their psychophysiological reactions. This approach is most important and will be further elaborated in the following section.

Treatment, Rehabilitation, and Prevention.—Investigation of the many factors correlated with various psychosomatic disorders ultimately leads to better treatment and control. A series of studies of emotional disorder associated with pregnancy and childbearing[11] has helped develop an apparently useful program of preventing or ameliorating postpartum emotional difficulties at the Englewood Hospital. A technique useful in alleviating these acute and usually short-lived puerperal disorders may not be exactly applicable to chronic psychosomatic disorders, but the method of investigation possibly may serve as a model with other illnesses.

In brief, this method was as follows. First, the life histories were studied of four groups of women: (1) those who suffered postpartum psychiatric disorders, (2) those who suffered milder postpartum upsets but who were managed without psychiatric help, (3) normal new mothers, and (4) married women of the same age who suffered psychiatric disorders unassociated with pregnancy.

First, the stressful life history features which separated the various groups were identified. Second, a prediction scale of significant life history items was developed and tested on new series of new mothers. It was found to identify in the aggregate the subsequently emotionally upset. Third, study of items correlated with emotional upset and their intercorrelations with each other led to development of hypotheses as to dynamics of the disorders. Fourth, a set of instructions to expectant parents was developed from these hypotheses which pointed to some of the potential dangers and suggested means of modifying the situation. This was put to test with quite successful results with the experimental as compared to the control groups of subjects. Fifth, responses of the subjects in relation to the recommendations of the instructions were measured and their intercorrelations with each other obtained. These are now leading to further improvements in the instructions.

A possible investigation of cardiac disorders, perhaps leading to improved rehabilitation and prevention, is now being planned at the Englewood Hospital, with this experimental design used as a model. It was hypothesized that the apparent success with postpartum patients was related to a method of instruction which demonstrated the realistic and practical steps to take to reduce stresses and strains that demonstrably precipitate emotional difficulties. Less may possibly be done in reducing the effect of early childhood sensitization and conditioning to emotional and psychosomatic disorders. But the previous study seemed to indicate that only two 40-minute classroom sessions of instruction in antenatal classes were quite effective in helping subjects make the necessary changes in their lives prior to delivery and in preventing postpartum emotional difficulties from developing. Perhaps increasing study of the important environmental stresses that precipitate other psychosomatic conditions, particularly coronary artery disease, in conjunction with many other approaches, may help develop practical information which will be useful in prevention, treatment, and rehabilitation.

Summary

Investigation was made of the comparative overall incidences of asthma, coronary thrombosis, duodenal ulcer, essential hypertension, and hypertensive cardiovascular disease in several communities which differ in mobility. The age distribution, sex pattern in 1957, and the change in pattern from 1950 to 1958 were also obtained. Bronchopneumonia was used as a comparison disorder.

Tension disorders were most prevalent in a rapidly growing suburban community and least prevalent in a stable rural area. Differences in incidence were highest and incidence rose the most in young married women in the period of rapid growth in the suburb. Asthma was more prevalent in Kingston, a community of many older people. Generally, older people had more psychosomatic illness in stable rural areas and younger persons had more in the growing suburb. The data support those found in other investigations of psychiatric inpatients and outpatients.

275 Grand Ave. (Dr. Gordon).

We appreciate the assistance in this study of Mr. Nelson R. Henson, hospital administrator, Miss Gladys Evans, director of public health services, and Miss Jean Tilt, record librarian, of Englewood Hospital; Mr. Richard A. Derr, hospital administrator, and Miss Alice B. Woodard, record librarian, of Olean General Hospital; and Mr. Robert M. Schnitzer, hospital administrator, and Miss Mary Lou Smith, record librarian, of Kingston Hospital. We are grateful to Dr. G. Barton Barlow of Englewood, who provided data from his own studies.

SOME PSYCHOSOMATIC ASPECTS OF ASTHMA

Charles L. Heiskell, M.D., John M. Rhodes, Ph.D.
and
Kent H. Thayer, M.D., Long Beach, Calif.

The validity of the hypothesis that asthma is a psychosomatic disease was tested in a study of 44 patients with bronchial asthma, 15 with allergic rhinitis, and 9 with pulmonary emphysema. All patients took the short form of the Minnesota Multiphasic Personality Inventory (MMPI). When the asthmatics were classified as to the severity of their dyspnea, a correlation was found indicating that the scales for hypochondriasis, depression, and hysteria reflected some variable related to the functional classification of the asthma. No comparable correlation was found with the amount of medication taken by the patient or the duration of the asthma. Asthma could be called a psychosomatic disease, but the possibility that some of the scores in the MMPI may actually be a more direct measure of symptoms requires further investigation.

Laennec was the first to propose that asthma is a neurosis dependent on either a functional or an organic change in the nerve centers.[1] This hypothesis has received increasing support until the present time, so that asthma is considered by some[2] to be a classic example of a psychosomatic disease.

Reports to date of the psychological traits considered characteristic of patients with asthma have, however, been conflicting. This conflict possibly results from variable diagnostic criteria for asthma, sampling of the asthma population, and psychological investigative techniques utilized.

One of the most widely used psychometric tools has been the Minnesota Multiphasic Personality Inventory (MMPI). It has been extensively investigated with respect to factor loading, reliability, and validity of the whole test and individual scales. Because of the literature available defining the limitations of this test,[3] it was thought that it might be of aid in the psychological study of a medically well-defined population of asthma patients.

If there is validity to the hypothesis that asthma is a psychosomatic disease, then analysis of the data obtained by a test that purportedly detects the psychological traits characteristic of such a disease should demonstrate these to be present to a significant degree in a group of patients with asthma.

Method

The MMPI scales were constructed by comparing the responses of patients with established psychiatric diagnoses with those of persons not under psychiatric care; these were termed as follows: hypochondriasis (Hs), depression (D), hysteria (Hy), psychopathic personality (Pd), paranoia (Pa), psychasthenia (Pt), masculinity-femininity of interest (Mf), schizophrenia (Sc), and hypomanic trends (Ma). The lie score (L) and validity score (F) are for determining the patient's understanding, cooperativeness, and tendency to place himself in a favorable light. The K scale is designed to increase the discriminatory value of the Hs, Pd, Pt, Sc, and Ma scales.[4]

The group studied consisted of 44 patients with bronchial asthma, 15 patients with allergic rhinitis, and 9 patients with pulmonary emphysema. All

---

From the Long Beach Veterans Administration Hospital Allergy Clinic and Allergy Research Laboratory.

were selected in sequence from the patients seen in the Long Beach Veterans Administration Hospital allergy clinic during a three-month period.

The diagnosis was established by the characteristic symptoms, physical findings, laboratory data, and skin reactions to allergens thought to be consistent with the patient's history. This limited the patients of the asthma group to those with a relatively well-defined allergic condition, and it is believed that no patients were included with significant pulmonary emphysema, bronchiectasis, congestive heart failure, or neurotic hyperventilation. The group with allergic rhinitis included no patients with evidence of such complications as deviated nasal septum or purulent sinusitis.

All patients with asthma and allergic rhinitis had been observed at weekly intervals for purposes of a therapy investigation for at least six months and had been carefully evaluated and classified on the basis of functional ability. The nine patients with pulmonary emphysema were selected in sequence from a group referred to the clinic because of dyspnea and wheezing. Their true diagnosis was established on the basis of pulmonary function studies and exclusion of asthma by absence of the characteristic history, symptoms, and significant skin reactions to allergens.

All patients were given the short form[5] of the MMPI and were allowed to complete it without time limitation. Absolute scores on the various scales were converted to standard score (TorTc scale) for purposes of comparison.

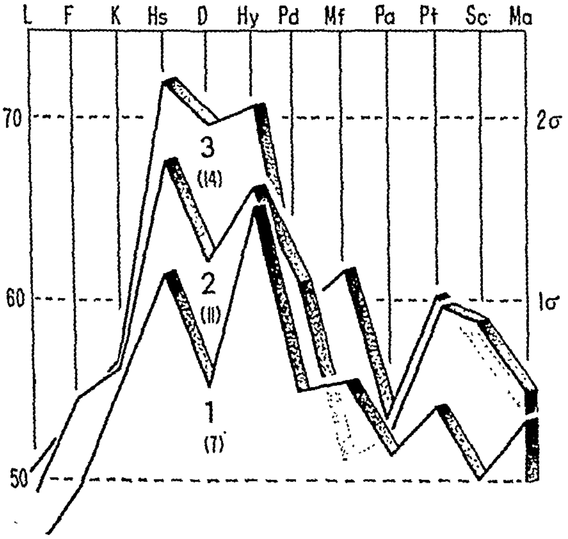

Fig. 1.—MMPI profiles of patients with asthma, functional classes 1, 2, and 3.

Results

The resultant mean profiles were determined for the subgroups of patients with allergic rhinitis, asthma, and pulmonary emphysema. The patients with asthma were arbitrarily subclassified into five groups at the time of testing on the basis of functional ability according to the following criteria as applied to the three-month period prior to testing: 1. The patient had definitely established asthma at some time in the past but no significant paroxysms. 2. The patient had occasional episodes of wheezing and dyspnea but not severe enough to require continued medication or interfere with sleep, daily activities, or regular work. 3. The patient had frequent paroxysms of wheezing and dyspnea severe enough to require medication at least weekly, causing occasional loss of sleep, occasional interference with daily activities, but less than one week's work loss due to asthma. 4. The patient had daily paroxysms of wheezing and dyspnea requiring regular medication, with moderate to marked interference with daily activities, and causing from one to three weeks' work loss due to asthma. 5. The patient had daily to continuous wheezing and dyspnea requiring constant medication, over two weeks' hospitalization for asthma, or over three weeks' loss of work due to asthma.

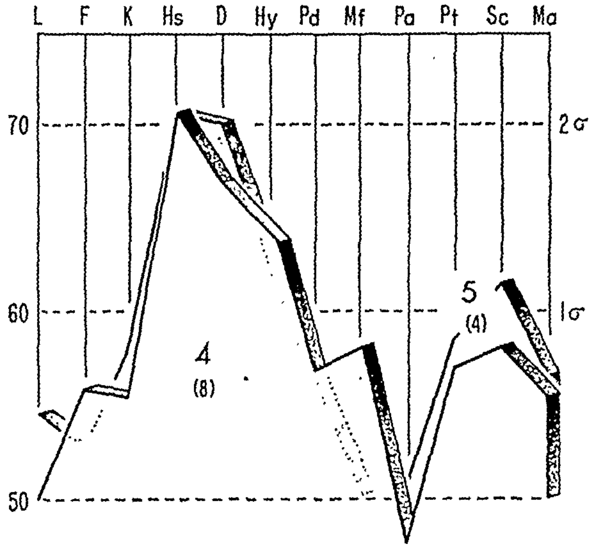

Fig. 2.—MMPI profiles of patients with asthma, functional classes 4 and 5.

Mean scores for patients with asthma in the various functional classes are shown in figures 1, 2, and 3. It is evident that those with asthma in functional class 1 show the so-called psychosomatic V (characteristic relationship of high scores for Hs, D, and Hy scales), with classes 2 and 3 showing progressively greater increases in these scores and retaining the same relative quantitative relationship among them. Classes 4 and 5 show no further increase in the Hs and D scores over those of class 3 but do show a relative decrease in the Hy score, with consequent disappearance of the psychosomatic V. (This phenomenon has been called "somatization" and is said to be a characteristic modification of the "conversion V" when an "organic," as opposed to a "functional," cause for symptoms is present.)

In order to compare the area of the psychosomatic V present in the different functional classes of asthma, the score $(\frac{Hs+Hy}{2})$—D was computed (see table) and compared to the functional class. There appears to be a close negative correlation between increasing functional impairment by group and the area of the psychosomatic V shown in the mean profiles. (The score $\frac{Hs+D+Hy}{3}$ has been said to be a measure of anxiety[6] and shows less correlation with degree of functional impairment than does the psychosomatic V.) These data would indicate that the Hs, D, and Hy scales and their interrelationships effectively reflect some variable related to the functional classification of asthma.

*Average Scores for Hs, D, Hy, Psychosomatic V, and Anxiety Scales for Patients with Allergic Rhinitis, Asthma, and Pulmonary Emphysema**

	MMPI Scales							Psychosomatic V, $\frac{Hs+Hy}{2}$—D	Anxiety, $\frac{Hs+Hy+D}{3}$
	Hs		Hy		$\frac{Hs+Hy}{2}$	D			
Group (No. of Patients)	Av.	S.D.†	Av.	S.D.		Av.	S.D.		
Allergic Rhinitis (15)	62.7	10.9	61.7	12.1	62.2	59.8	11.0	2.4	61.4
Asthma, functional class									
1 (7)	61.5	12.3	65.1	10.5	63.3	55.1	8.1	8.2	60.6
2 (11)	67.6	12.7	66.2	9.0	66.9	63.5	10.0	3.4	65.8
3 (14)	71.9	13.8	70.5	8.5	71.2	69.5	8.6	1.7	70.6
4 (8)	70.5	11.3	63.7	12.0	67.1	66.8	12.0	0.3	67.0
5 (4)	70.5	18.5	61.2	15.0	65.8	70.0	12.8	—4.2	67.2
Pulmonary emphysema (9)	82.8	18.0	73.1	9.7	75.8	71.5	11.5	4.3	77.9

* Hs = hypochondriasis, D = depression, Hy = hysteria.

† S.D. = standard deviation.

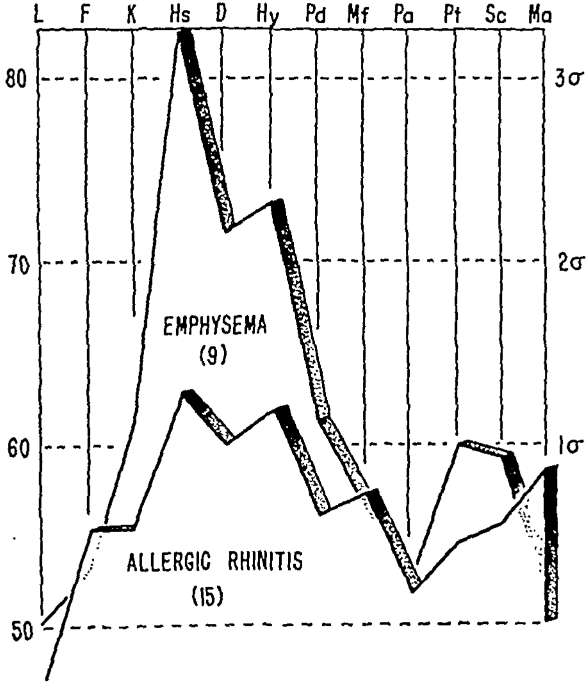

Fig. 3.—MMPI profiles of patients with allergic rhinitis and pulmonary emphysema.

The group with pulmonary emphysema showed a profile with the greatest deviation from the normal mean (fig. 3) but it still retained a definite similiarity to profiles of the first three functional classes of asthma so far as the Hs, D, and Hy scales were concerned. The group with allergic rhinitis had a profile which also resembled those in the first three functional classes of asthma, particularly functional class 1, in which the patients had been asymptomatic for three months prior to taking the test.

Since patients with asthma have a functional capacity at least partially dependent on the amount of medication they receive, they were also arbitrarily subclassified on the basis of therapy received according to the following criteria, as applied to the three-month period prior to testing: 1. The patient needed and took no medication. 2. The patient took only occasional doses of sympathomimetic drugs orally. 3. The patient regularly took sympathomimetic drugs orally, with occasional, but not regular, use of sympathomimetic nebulization or aminophylline suppositories. 4. The patient regularly took sympathomimetic drugs orally, used sympathomimetic nebulization daily, and received epinephrine injections not more than once weekly. 5. The patient took any or all of the above medicaments but received an average of more than one epinephrine injection weekly or was on long-term steroid medication. There appeared to be no significant correlations between MMPI scores and therapeutic classification.

Patients were also classified into four groups according to duration of their asthma, and the mean scores were computed. Again, there appeared to be no significant correlation between this factor and the MMPI scores.

Comment

It is evident that patients with asthma show an MMPI profile with characteristically high scores for the Hs, D, and Hy scales, in a relationship which has been called the psychosomatic V. On the basis of this consistent finding asthma could, therefore, be called a "psychosomatic" disease. It is further evident from these data that the closest correlation of this phenomenon is found to be with the degree of the patient's functional impairment or the severity of his illness. Patients with allergic rhinitis, who were comparatively unimpaired in relation to significant interference with sleep, daily activities, and ability to work, showed a profile similar to that of patients with asthma in functional class 1, who were also comparatively unaffected by their disease during the three months prior to testing. The remaining functional classes of patients with asthma showed increasing scores on these scales as the degree of functional impairment increased. The patient with pulmonary emphysema, with no evident allergic disease but with similar symptoms and even greater functional impairment than the patients with asthma, showed the greatest increase in these scores (and could also be said to have a psychosomatic disease).

All objective supportive evidence, including positive family history of allergy, associated allergic stigmata such as urticaria and allergic dermatitis, and number and intensity of positive skin reactions to allergens, indicated that the patients with allergic rhinitis were equally as "allergic" as the patients with asthma. The patients with pulmonary emphysema had no demonstrable allergy. If these groups are arranged in a continuum from the one having no significant functional impairment to the one most severely impaired, it is evident that the degree of profile deviation from the normal mean is more closely correlated with symptom severity than presence of allergic disease. It is further evident that, in the patients with asthma, the psychosomatic pattern of the profile progressively decreases as symptom severity increases.

It is possible that this unexpectedly close correlation between the patient's symptom severity and type of MMPI profile may arise from anxiety over symptoms. It has been suggested that the Hs, D, and Hy scores will serve as a rough measure of anxiety.[6] The mean anxiety scores for the groups studied are given in the table. It is evident that this score does not show so close a relationship to functional impairment as does the psychosomatic V.

An alternative explanation of some of this correlation is that a portion of the Hs, D, and Hy scores may actually be a more direct measure of symptoms. This hypothesis is currently under investigation. Complete determination of the factors responsible for these scores in patients with asthma will be evident from an item analysis of these responses, as well as other psychometric and projective techniques presently in use in this clinic to investigate the psychological traits of the patient with asthma.

Summary

Study of a well-defined population with bronchial asthma with use of a well-known psychometric tool, the Minnesota Multiphasic Personality Inventory (MMPI), indicated that the "psychosomatic" profile is more closely correlated with the degree of functional impairment than the presence or absence of allergic disease.

5901 E. Seventh St. (4) (Dr. Heiskell).

Mrs. Elsie Carruthers and Miss Arden Knaak assisted in test administration, scoring, and data compilation.

STAPHYLOCOCCI WITHIN PHAGOCYTIC CELLS.—Some years ago we noted that pathogenic staphylococci were steadily ingested by human leukocytes in systems in which other virulent microbes failed to be phagocytosed. Despite the fact that virtually all staphylococci were ingested by leukocytes, little or no killing of staphylococci could be detected. Subsequent studies indicated that certain staphylococci could survive for long periods within both human and rabbit polymorphonuclear leukocytes and that this ability correlated well with . . . pathogenicity. . . . Strains of coagulase-positive staphylococci isolated from human infection invariably survived for four to five hours within the interior of polymorphonuclear leukocytes. In contrast, coagulase negative strains isolated from the skin, air, or anterior nares were almost uniformly killed within leukocytes during this time period. A sharp differentiation could thus be made between these two . . . species of staphylococci. Subsequent studies by Tompsett showed that such pathogenic staphylococci could also survive within mononuclear phagocytes obtained from rabbits while nonpathogenic strains did not.—D. E. Rogers, Observations on the Nature of Staphylococcal Infections, *Bulletin of the New York Academy of Medicine,* January, 1959.

FATALITY AFTER INJECTION OF SCLEROSING AGENT TO PRECIPITATE FIBRO-OSSEOUS PROLIFERATION

Richard C. Schneider, M.D., Jack J. Williams, M.D.
and
Leopold Liss, M.D., Ann Arbor, Mich.

A 50-year-old woman with a long history of lumbar and sciatic pain had only temporary and incomplete relief after conventional treatment. An attempt was made by another physician to stabilize the joints concerned by injecting a sclerosing solution into the ligaments about the lumbosacral joint. There was immediate pain, paralysis, and incontinence. In the following months symptoms of basilar arachnoiditis and hydrocephalus appeared. The patient was referred to the authors for treatment. Ventriculostomy, decompressive craniotomy, and other measures for reducing intracranial pressure failed because of the extensive adhesions. The sites described for the injection of the sclerosing solution lie near several dangerous areas where a needle might enter the subarachnoid space. This technique for stabilizing intervertebral and paravertebral joints is extremely unsafe.

In 1956 a monograph was published which indicated that the cause of low back pain in many patients was relaxation of the ligaments about the joints of the spine and pelvis.[1] The treatment advocated was the intraligamentous injection of a proliferating solution of the sodium salt of a vegetable oil fatty acid to develop a maximum amount of fibrous tissue and bone, thereby affording joint stabilization. At the time of publication of the monograph, 4,000 injections of such a solution had been made "within the ligaments of a variety of articulations with no unfavorable incident or sequelae." Cures were reported for over 90% of the patients treated.

Although this form of therapy, namely, the injection of a fibro-osseous proliferating solution into the joints, has been without unfavorable incident in the hands of its author, the case reported here demonstrates one of the possible tragic complications of such therapy undertaken by another practitioner using this method.

Report of a Case

A 50-year-old woman had intermittent attacks of low back pain and sciatica bilaterally for 15 years. Her discomfort was not accentuated by coughing, sneezing, or straining at defecation. There had been several episodes of minor trauma to the spine, but there was no single major precipitating factor responsible for her symptoms.

She was able to bend forward, tilt toward either side, and bend backward readily. A straight leg raising test gave negative results on the right side to a 90-degree angle; the results appeared to be positive at a 30-degree angle on the left side. Dorsiflexion of the foot accentuated her pain. However, when her attention was diverted, the left thigh could be flexed on the abdomen and the leg extended completely without discomfort. At that time, dorsiflexion of the foot caused no sciatic pain. There were no sensory or reflex changes. Her spinal fluid protein level was 44 mg.%. The patient improved on two occasions on a regimen of pelvic traction, bed boards, bed rest, a back brace, and sedation; but later she developed intermittent recurrence of her symptoms.

In June, 1957, the patient had her case reports transferred to a physican in another community who was using the injection technique for creating fibro-osseous proliferation of the ligaments with presumed stabilization of the joints. After a diagnosis of unstable ligaments of the back had been made, the patient was placed in a prone position on the table, the site of the lumbosacral joint was identified, and the solution (stated to be zinc sulfate in 2.5% phenol solution) was injected in the midline into the ligaments about the lumbosacral joint. She developed immediate severe pain in the legs, was paralyzed from the waist downward, and had loss of bladder control. On attempting to arise from the table she fell to the floor. She was hospitalized for several days at two hospitals in that community. During this time she gradually regained almost complete use of her legs, although from the time of injection she continued to require an indwelling catheter for bladder function and cleansing enemas for bowel care. Eventually she was discharged to her home for convalescence.

In September, 1957, the patient was treated at St. Joseph Mercy Hospital in Ann Arbor for severe cystitis and nephritis. On Oct. 27, 1957, she was readmitted to the hospital complaining of nausea, vomiting, paresthesias over the buttocks and legs,

---

From the Department of Surgery, Section of Neurosurgery, and Department of Neuropathology, University of Michigan Hospital and St. Joseph Mercy Hospital.

perioral numbness, blurred vision, headaches, and generalized malaise. She had developed diplopia due to a right sixth nerve palsy. On examining the fundi, 2 D. of papilledema were found, with retinal hemorrhages and engorged retinal veins bilaterally. She had a mild peripheral facial paresis on the right, progressive weakness of the right leg, nuchal rigidity, and slurred speech. A diagnosis of basilar adhesive arachnoiditis was made.

On Nov. 1, 1957, ventriculograms demonstrated a widely dilated ventricular system. Unfortunately the anteroposterior and occipital views were unsatisfactory. The so-called Swedish views taken in the anteroposterior and posteroanterior position with a horizontal beam exhibited a marked degree of hydrocephalus (fig. 1). In the brow-down view not only was air seen in the occipital horns but some was seen in the cisterna magna (fig. 2). This suggested the presence of a communicating hydrocephalus. Because of the markedly increased intracranial pressure, a ventriculostomy on the left side was performed to gradually decompress the brain and adjust it to pressure changes. The ventricular fluid contained 704 red blood cells and 493 lymphocytes per high-power field. The fact that the patient continued to have moderate hypertension in spite of 24 hours of ventricular drainage was regarded as an ominous prognostic sign.

On Nov. 4, 1957, with the patient under intratracheal general anesthesia, exploration of the posterior fossa was performed. Immediately after the positioning of the patient on the operating table, marked hypotension developed which had to be combated by tilting her into the extreme Trendelenburg position and administering phenylephrine (Neo-Synephrine) hydrochloride intravenously. Her vital signs were permitted to stabilize for an hour. Inasmuch as the patient's condition had deteriorated in spite of ventriculostomy during the 48 hours prior to operation, it was believed that she would not improve further and that this would be the last chance afforded her for relief of blockage of the cerebrospinal fluid due to adhesions at the cisterna magna. Therefore, suboccipital craniotomy was performed. When the posterior fossa was exposed and the dura opened, a markedly adhesive arachnoiditis was found about the rim of the cisterna magna.

Indigo carmine was injected into the ventricular system at the site of the posterior parietal ventriculostomy on the left. The contrast medium readily appeared in the fourth ventricle but could not flow beyond the cistern because of marked adhesions. These were separated with difficulty. A small rubber catheter could be passed upward through the aqueduct into the third ventricle without difficulty. Several attempts were made to enter the subarachnoid space at the base of the brain, but the adhesive arachnoiditis prevented stripping of membrane from the cerebellar hemisphere or the region of the cerebellopontine angle. It was therefore considered advisable to close the wound, leaving the ventriculostomy tube in situ, and in a few days perform a shunting operation to overcome the hydrocephalus. At the close of the operation the patient's blood pressure had stabilized to some degree but only with the aid of a continuous intravenous phenylephrine drip.

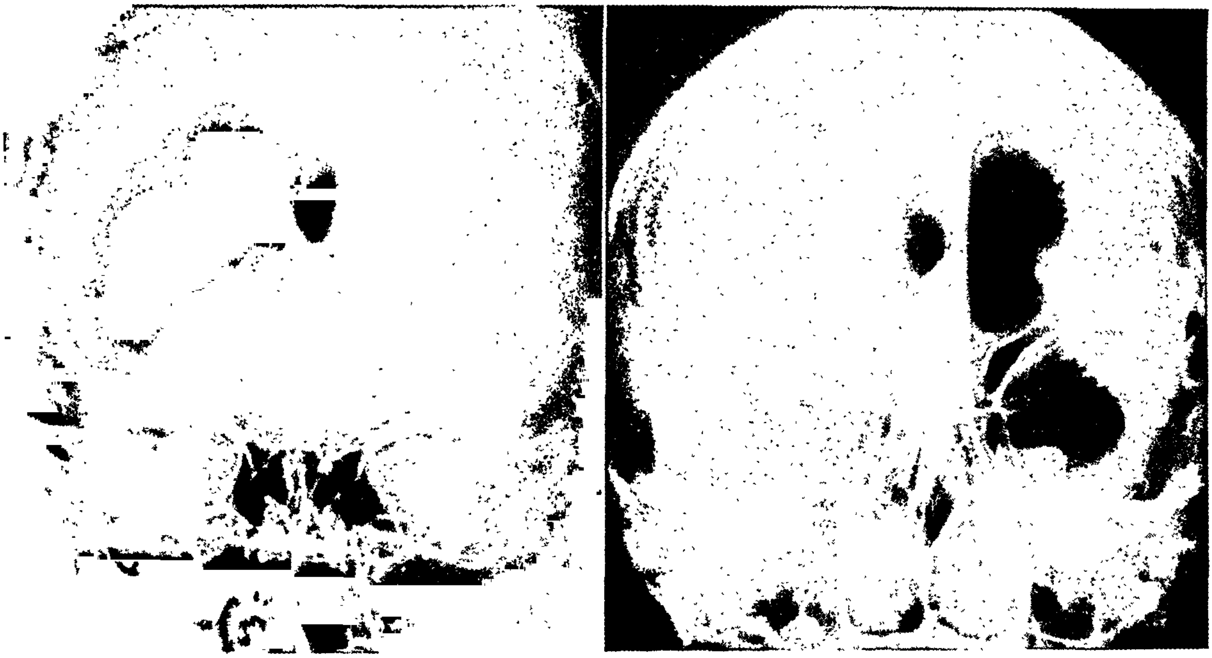

Fig. 1.—*Right*, anteroposterior and, *left*, posteroanterior ventriculographic views showing marked hydrocephalus.

Immediately after transfer of the patient from the operation table to the stretcher, it was observed that the pupils were dilated and had only a very faint reaction to light. This finding was thought to be due to cerebral anoxia secondary to the prolonged period of hypotension. It was believed that the adhesive arachnoiditis process had extended over the entire cerebrum and perhaps was responsible for widespread cerebral damage. In the recovery room the patient regained consciousness from anesthesia. Her reflexes were markedly obtunded and she was suffering from receptive and expressive aphasia. For the next six hours, vital signs were within a satisfactory range. However, at 7:30 p. m. her blood pressure abruptly rose to 220 mm. Hg systolic level and there were Cheyne-Stokes respirations. A large amount of cerebrospinal fluid had drained from the ventricular system through the ventriculostomy. In spite of the prompt administration of 100 cc. of 50% dextrose solution, the patient developed apnea and died suddenly at 8:10 p. m.

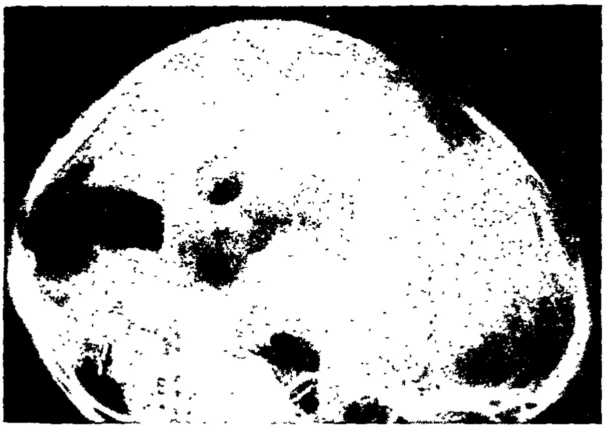

Fig. 2.—Brow-down ventriculographic view demonstrating dilated occipital horns and air in cisterna magna (*arrow*).

Postmortem Examination

At autopsy the entire spinal cord with the dura was removed by a posterior approach. There were some gross adhesions between the dura and inner meninges. An extradural hematoma found between the occipital bone and the dura measured 6 by 8 cm. and contained approximately 90 cc. of clotted blood. The inner meninges were not greatly thickened. The brain showed flattening of the convolutions and narrowing of the sulci due to cerebral edema. In the region of the parietal lobe the rubber catheter used in the ventriculostomy was demonstrated passing through the cerebral cortex into the left lateral ventricle, which was slightly dilated. The pons and medulla were symmetrical, with equivocal gross evidence of an adhesive arachnoiditis.

Microscopic Examination.—There was both an acute and chronic pattern observed in the study of this brain and spinal cord. Acute inflammatory changes were limited to the base of the brain in the posterior fossa and the upper cervical spinal cord.

Around the major vessels near the fourth ventricle there was perivascular infiltration. The choroid plexus was markedly infiltrated (fig. 3). The brain tissue exhibited some edema and generalized gliosis. In the lateral ventricles there was marked subependymal gliosis with astroglial proliferation and nodule formations in the ependymal layers. Granular ependymitis was demonstrated in the floor of the third and fourth ventricles.

The lower part of the spinal cord was markedly edematous and showed active gliosis with degeneration of numerous nerve fibers. The most marked chronic changes were demonstrated in the spinal cord. The dura and meninges had fused together and were frequently indistinguishable. The spinal meninges had compressed the cord and anterior and posterior spinal roots (fig. 4). No signs of acute inflammation were seen in the cauda equina. Here the connective tissue was dense, acellular, and partially hyalinized, with the most conspicuous feature being the marked connective tissue proliferation around the blood vessels, representing an old chronic periarteritis (fig. 5).

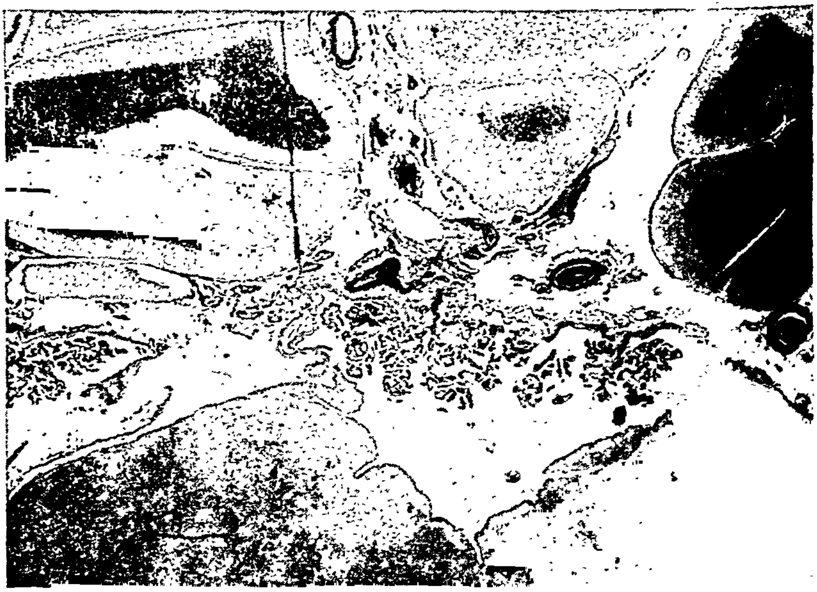

Fig. 3.—Area of fourth ventricle. Pronounced acute inflammatory changes (fibrin and cellular infiltration) of cerebellar meninges and choroid plexus.

The acute and chronic pathological pictures were independent of each other and could easily be separated, since the chronic scarification process was of an ascending nature and most pronounced around the lowest spinal cord segments. These findings definitely increased around the medulla, cerebellopontine angle, and the base of the brain. On the other hand the acute inflammatory changes, which were apparently secondary to the introduction of the ventriculostomy tube, the rubber catheter, and the indigo carmine contrast medium, were most marked in the posterior fossa and could be detected as isolated foci at the medullary and upper cervical levels. The continuous spread of the inflammation was apparently stopped by previous obliteration of the subarachnoid space.

Comment

The pathological specimens indicated diffuse involvement of the entire central nervous system. This patient was doomed at the very onset, regardless of the approach made to her problem. Although the sclerosing solution was injected accidentally into the subarachnoid space, the general pattern of the neurological complications followed rather closely those due to adhesive arachnoiditis secondary to some substances which have been deliberately introduced into the space for diagnostic, anesthetic, or therapeutic purposes.

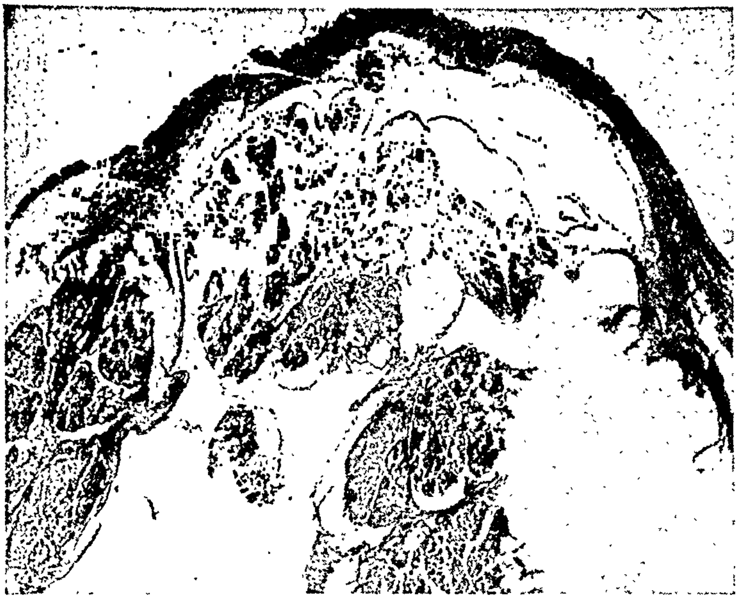

Fig. 5.—Cauda equina. Marked proliferation of perineural connective tissue.

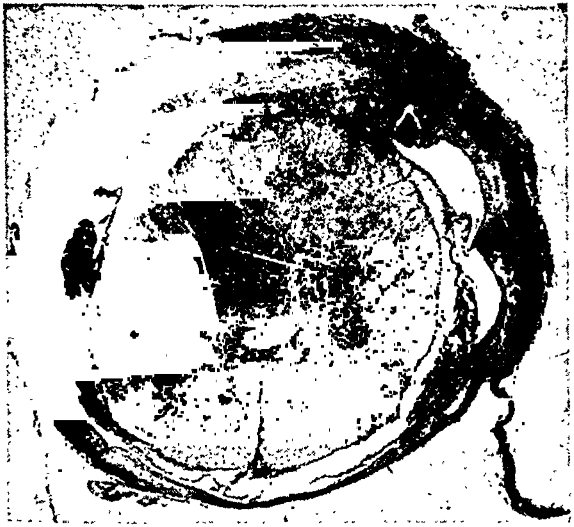

Fig. 4.—Spinal cord with dura and pia fused together. Note posterior root ganglions embedded in proliferated connective tissue.

Kennedy and others called attention to the grave complications involving the central nervous system, associated with spinal anesthesia, when they reported 3 cases [2] in 1945 and subsequently added 12 more case reports [3] in a comprehensive review of the topic in 1950. They indicated that the time interval between the actual injection of the anesthetic and the development of the lesion may be so great that the connection between cause and effect is not realized by the anesthetist or the surgeon.

Paddison and Alpers [4] presented a case of adhesive arachnoiditis occurring after spinal anesthesia, but they attributed this lesion not to the anesthetic agent but rather to the detergent cleaning material used. The entire neuraxis was involved in a progressive process with its onset 24 to 48 hours after the administration of the anesthetic agent and its termination in death 63 days later, a day after the patient had ventriculography for a marked internal hydrocephalus. The posterior fossa was not explored. A complete postmortem examination included a description of the pathological changes in the spinal cord and brain stem.

Erickson and Baaren [5] published a report of a 33-year-old man who for two days after myelography had a fever and a flushed face but recovered completely. For nine months he was asymptomatic, but then he developed neurological signs and symptoms due to an exudate adhesive arachnoiditis which produced obstruction of the fourth ventricle and basilar cisterns, leading to death 15 months after the myelogram had been taken.

The latter two cases are very similar to the one reported here in that there was a brief acute phase of disability and then a relatively silent period during which the adhesive arachnoiditis insidiously progressed. There was diffuse involvement of the entire neuraxis with complete involvement not only of the spinal cord but even of the brain stem, with sealing off of the ventricular system and internal hydrocephalus culminating in death.

A careful review of the sites described for the injection of the sclerosing solution to develop fibro-osseous proliferation[1] revealed that there are several very dangerous areas where a needle might penetrate the dura and enter the subarachnoid space. This might easily occur directly at the lumbosacral joint or laterally in the subarachnoid space of the cuff or sleeve of the nerve roots. In the prescribed technique it is stated that a solution of local anesthetic is injected just in advance of the sclerosing solution. This, of course, removes all pain and permits a painless injection.

In the instance reported here it must be emphasized that the sclerosing solution was not the usual sodium salt of the vegetable oil fatty acid as described in the original monograph but instead a solution of zinc sulfate in 2.5% phenol solution. However, it matters little what sclerosing solution was used, for it would effect its proliferative response in any type of tissue into which it was injected. The amount injected (reported as approximately 2 cc.) seems minute enough, but even when diluted by the complete cerebrospinal fluid content throughout the entire subarachnoid space it was sufficiently powerful to have its devastating effect on the whole neuraxis. Firm adherence to the arachnoid has a constricting effect not only on the neural tissue itself but also on the vascular supply to the brain and spinal cord.

In treating this patient, the neurosurgeons found themselves caught in the unenviable situation of trying to correct an impossible situation, i. e., to relieve increased intracranial pressure in a truly hopeless lesion. The extradural hematoma of the posterior fossa in this case must be listed as an operative complication and immediate cause of death. It no doubt was due to hemorrhage from a large vein which was not bleeding at the time of wound closure but which subsequently opened to fluctuations in the continuous artificially supported blood pressure by the administration of vasopressor agents.

Summary

A patient with low back pain and leg pain was accidentally injected with a sclerosing solution into the thecal canal. It is tragic that the solution entered the subarachnoid space and caused an extensive adhesive arachnoiditis of the entire brain and spinal cord with the development of a noncommunicating hydrocephalus. An attempt at surgical correction of this apparently hopeless situation resulted in death. This technique of precipitating fibro-osseous proliferation appears to be neither sound nor without extreme danger.

FORMALDEHYDE IN WRINKLE-PROOF APPAREL.—Although it is rare, the following letter demonstrates that tears for milady may have an unemotional source. "There is some sort of gas—or condition—in the dress store I manage that causes our employees to have burning, stinging eyes and headaches. Customers coming into the store are also affected." . . . Many possible sources were investigated; ammonia leaks from refrigerators, freon gas escaping from air conditioners, gaseous products of combustion given off by heating appliances and even sewer gas. Not guilty! . . . The Ohio Department of Health had an inkling of the trouble—formaldehyde gas. . . . Health agencies in New York and Baltimore had reported similar complaints from cloth finishing mills and dress shops. Moreover, the physical symptoms and reactions of the people working in the dress shops matched the recorded symptoms caused by exposure to formaldehyde gas. . . . The air, in several dress shops from which complaints had been received, was tested for formaldehyde gas. Sure enough, the air did contain from 0.13 to 0.45 parts of formaldehyde per million parts of air. Not enough to cause illness, but sufficient to be intensely irritating.—H. B. Bourne Jr. and S. Seferian, Formaldehyde in Wrinkle-proof Apparel Produces Tears for Milady, *Industrial Medicine and Surgery,* May, 1959.

RESPONSE OF TRIGEMINAL NEURALGIA TO "DECOMPRESSION" OF SENSORY ROOT

DISCUSSION OF CAUSE OF TRIGEMINAL NEURALGIA

W. James Gardner, M.D.
and
Michael V. Miklos, M.D., Cleveland

Two series of patients with tic douloureux were followed up after surgery. In one series of 100 patients (Cleveland series) the extradural approach was used and the sensory root of the trigeminus was freed from its dural sleeve and otherwise manipulated; in the other (Copenhagen) series of 100 patients the approach was intradural, was less apt to traumatize the semilunar ganglion, and caused less postoperative sensory impairment. In the combined series, 62% of the patients reported complete relief, 11.5% had mild recurrences, and 26.5% had severe recurrences. Some degree of sensory loss was present in 26% with successful treatment and in 28.3% of those in whom the treatment failed. Neither surgical trauma to the nerve root nor incision of its dural sleeve were essential to the success of the operation. The critical part of the operation appeared to be a neurolysis or manipulation of the sensory root at the point where it crosses the apex of the pars petrosa of the temporal bone.

Decompression of the sensory root was performed on 112 patients with trigeminal neuralgia (tic douloureux) between January, 1953, and March, 1955. Two of these patients died in the hospital and 10 were lost to follow-up within one year. The remaining 100 patients, with the exception of 5 who died in the interval, were followed for three and one-fourth to five and one-half years and constitute the basis of this analysis.

Results of Decompression Operation

Sixty-seven patients had no paroxysm of tic douloureux after recovery from anesthesia of the operation. Of the remaining 33, 8 have had only mild recurrences and are happy with the result. For 25 patients the initial operation failed to afford satisfactory or lasting relief. Two of these patients, because of continuing pain while still in the hospital, required a revision of the operation. The revision, consisting of reexposure and further manipulation of the nerve root, was followed by lasting relief in one patient and by mild recurrence after three and one-half years in the other; however, because a second procedure was required these two cases have been classified with the failures. Twenty-three patients experienced severe recurrences after a postoperative period of relief, and 19 of them had subsequent operative procedures. Six of these had a second decompression, followed in four instances by a second recurrence. (One of these latter patients has severe multiple sclerosis with bilateral trigeminal neuralgia and refused to have the second nerve cut. Dividing the great auricular nerve, after the method of Wyburn-Mason,[1] was without effect.) Ten had resection of the sensory root, one alcohol injection, and two exploration of the nerve in the posterior fossa. In one of the latter patients, an anomalous arterial loop was found lying against the nerve; the pain was completely relieved after separating this vessel from the nerve root by the interposition of a piece of absorbable gelatin sponge (Gelfoam). In the second patient the pain was relieved after the removal of a large meningioma attached to the lateral sinus on the side of the pain. Of 33 patients with recurrence or persistence of pain, therefore, 21 have had reoperation and 12 have not. In eight of the latter the recurrence thus far has been so mild that reoperation has not been indicated.

Of the 67 patients who had complete and lasting relief after decompression, 7 exhibited sensory loss before operation because of previous treatment. Of the remaining 60, 23 (38%) had postoperative subjective numbness or demonstrable sensory loss or both. Of the 33 patients who had a mild or a severe recurrence, 3 exhibited sensory loss from previous treatment. Of the remaining 30, 13 (43%) had postoperative subjective numbness, demonstrable sensory loss, or both. These comparative percentages indicate that impairment of sensation resulting from trauma of the operation was not a factor contributing to the success or failure of the operation.

Read before the Clinical Congress of the American College of Surgeons, Chicago, Oct. 10, 1958.

Operative Methods

These patients were operated on by one surgeon (W. J. G.) using the extradural approach of Frazier with the patient in the sitting position. After the dura had been opened anterior to the petrous ridge, the dural sheath over the sensory root was incised back through the petrosal sinus into the tentorium for a distance of 1 cm. posterior to the apex of the petrous portion of the temporal bone. The sensory root was freed from its dural sleeve, gently brushed with a cotton pledget, and irrigated with Ringer's solution.

Taarnhøj, using his intradural approach with the patient in the horizontal position, followed 100 patients in his Copenhagen series for three to six years.[2] Fifty-seven of these patients had no recurrence of tic pain, while in 15 the recurrence was so mild that the operation could be considered successful. In 28 cases, the operation failed to afford satisfactory or lasting relief. Nine of these patients had a second decompression, nine had resection of the sensory root, and eight had alcohol injection; two did not have reoperation.

Fewer patients in the Copenhagen series than in the Cleveland series exhibited postoperative sensory impairment. It was present in 14% of those with a good result and in 11.6% of those in whom the treatment failed. The lower incidence of sensory loss in the Copenhagen series probably is due to the fact that the intradural approach is less apt to result in trauma to the ganglion.

Considering the Cleveland and the Copenhagen series together, 62% had complete relief, 11.5% had mild recurrences, and 26.5% had severe recurrences. Some degree of sensory loss was present in 26% with successful treatment and in 28.3% of those in whom the treatment failed. These figures indicate that sensory loss is not essential to success and, therefore, that the relief of pain is not the result of interruption of nerve impulses. That trigeminal neuralgia can be immediately relieved by an atraumatic manipulation of the nerve root suggests that the cause of this pain, whatever it may be, is located in this portion of the trigeminal system.[3]

Other intracranial operations on the trigeminal system that do not sever the nerve have afforded relief from trigeminal neuralgia. Sheldon and associates[4] described relief by an intracranial "decompression" of the second and third divisions of the nerve; they accomplished this by enlarging the foramens of exit with a dental drill. They subsequently discovered that trigeminal neuralgia could be relieved more effectively by "compression" of the posterior root than by decompression of its peripheral branches and that incision of the dural sheath was not essential to success. Therefore, they concluded, the relief of pain in these cases was due to surgical trauma to the nerve rather than to relief of pressure as Taarnhøj had hypothesized. Stender[5] relieved trigeminal neuralgia by opening the cavum mecklii, an operation which he described as "gangliolysis." However, regardless of the terms applied to them, the common feature of these intracranial procedures is manipulation of the sensory root. Even the retraction of the dura incident to introducing a dental drill into the foramen rotundum or ovale is bound to exert some indirect traction on this structure.

That the relief is due to manipulation (neurolysis) of the sensory root and not to compression or decompression of the root, the ganglion, or the peripheral branches is indicated by an experience which Taarnhøj[6] described as follows: "In some patients with trigeminal neuralgia in this series, suspected to have tumors in the cerebellopontine angle, a cerebellar approach was performed, but no tumor was found. . . . A hook then was put into the porus trigemini—i. e. the opening where the root leaves the cavum Mecklii—and an attempt was made to enlarge the porus a little in different directions in order to free the root from possible adhesions. Although no real decompression was performed in the 5 patients treated in this way, they were all free from pain after the operation, and the sensibility was normal." This author, therefore, has shown that, via either a middle or a posterior fossa approach, trigeminal neuralgia may be relieved by a manipulation of the sensory root carried out so gently that no sensory loss results.

In 627 operations for trigeminal neuralgia via the middle fossa, Ruge and co-workers[7] found six meningiomas of the dural envelope of the gasserian ganglion. In 473 operations via the posterior fossa at the Johns Hopkins Hospital,[8] 24 tumors were encountered. These two series indicate that trigeminal neuralgia is associated with a tumor located in the middle fossa (1%) or in the posterior fossa (5%). Inasmuch as the posterior root constitutes the only part of the trigeminal system common to both fossae, this again suggests that the cause of the pain is located in the posterior root.

Comment

The tendency to consider trigeminal neuralgia a disease rather than a symptom has obscured thinking on the subject. Harris,[9] for instance, found it to be a "complication" of multiple sclerosis in 64 of 1,622 cases; in one such case studied at autopsy, Parker[10] demonstrated a sclerotic plaque on the sensory root.

Where tumors, anomalous blood vessels, or other obvious lesions involving the nerve are not present in cases of trigeminal neuralgia, there still remains the anatomic fact, pointed out by Lee,[11] that in man the sensory root of the nerve is angulated at the point where it crosses the apex of the petrous bone. In a roentgenographic study of the skulls of 130 patients with trigeminal neuralgia, Gardner and co-workers [12] measured the relative heights of the apexes of the petrous bones at this point. In 60% of the patients the apex of the petrous bone on the neuralgic side projected higher into the cranial cavity than it did on the opposite side, while in only 20% was this relationship reversed. Their studies also showed that a progressive upward migration of the dens occurs between the fourth and eighth decades in women with trigeminal neuralgia. This progressing basilar impression, they believed, was due to postmenopausal osteoporosis. In these cases the apex of the right petrous bone was usually pushed higher into the cranial cavity than the left, and this was advanced as a possible explanation for the fact that trigeminal neuralgia is more commonly encountered on the right side and in elderly women. These authors pointed out that trigeminal neuralgia also may be a symptom of basilar impression of the congenital variety or of the acquired form that accompanies Paget's disease of the skull.

In view of the evidence cited above we believe that the cause of trigeminal neuralgia may be localized to the posterior root of the fifth cranial nerve with almost as much certainty as the cause of brachialgia and sciatica may be localized to the posterior root of a spinal nerve. In this connection it is interesting to note that Frykholm,[13] also a Scandinavian, relieved brachialgia by incising the dural sheath of the angulated sensory root of the spinal nerve just as Taarnhøj, some years later, relieved trigeminal neuralgia by incising the dural sheath of the angulated sensory root of the trigeminal nerve.

Because trigeminal neuralgia can be relieved by alcohol injection of a peripheral branch of the nerve, Rowbotham [14] and others have suggested that the cause is peripheral to the ganglion. This theory is countered by the fact that, even though trigeminal neuralgia associated with a tumor in the posterior fossa can be relieved temporarily by a peripheral alcohol injection, it can be permanently relieved by a removal of the tumor carried out so carefully that it produces no sensory loss.[15]

In 1937, Frazier and associates [16] suggested that the lesion responsible for trigeminal neuralgia lies in the thalamic-cortical connections. Recently, King and co-workers [17] advanced experimental evidence that suggests that the cause of trigeminal neuralgia could be in the descending nucleus of the trigeminal nerve. These theories, however, fail to explain why trigeminal neuralgia may constitute a symptom of a tumor compressing the nerve root and why the "idiopathic" variety can be immediately relieved by manipulation of the root where it crosses the apex of the petrous bone. Even the evidence advanced by Wyburn-Mason [1] that this pain may be relieved in some cases by resecting the great auricular nerve does not render the root theory of origin invalid. It indicates that the trigger mechanism in some patients is supplied, in part, by fibers of the cervical plexus that overlap the distribution of the trigeminal nerve.

In view of Dandy's [18] demonstration of the frequency with which the posterior fossa approach will disclose a cause for trigeminal neuralgia, it is not surprising that the middle fossa approach of Taarnhøj frequently fails to afford lasting relief. Therefore, it is now our custom to search for a lesion in the posterior fossa in those patients who develop a recurrence of trigeminal neuralgia after a neurolysis of the sensory root in the middle fossa. If the approach via the posterior fossa does not disclose a lesion, the nerve root is gently manipulated with a nerve hook introduced into the dural foramen, as practiced by Taarnhøj.[6] The results of this method of dealing with recurrences will be reported when an adequate follow-up sample is available.

Summary

A three-to-six-year follow-up study of 200 patients in whom "decompression" of the sensory root was done for trigeminal neuralgia (tic douloureux) revealed that 62% had complete relief, 11.5% had partial relief, and in 26.5% the operation failed. Neither surgical trauma to the nerve root nor incision of its dural sleeve is essential to its success. The critical part of the operation appears to be a neurolysis or manipulation of the sensory root at the point where it crosses the apex of the petrous bone.

Trigeminal neuralgia is a symptom—not a disease. It may constitute a symptom of multiple sclerosis, of basilar impression, or of a tumor located either in the middle or in the posterior fossa. "Idiopathic" trigeminal neuralgia may be relieved by a gentle manipulation of the sensory root via either a middle or a posterior fossa approach. The only portion of the trigeminal sensory system that is common to both the middle and the posterior cranial fossae is the sensory root. The cause of trigeminal neuralgia, therefore, presumably lies in the sensory root.

CANCEROPHOBIA AND DELUSION

Carl H. Fellner, M.D., Madison, Wis.

There are two types of patients who consult physicians in connection with the fear of having cancer and in whom malignancy cannot be detected. Those who fall into the cancerophobia classification can accept reassurance and regain normal status. Those who present the delusion of cancer are unable to accept reassurance and become increasingly anxious. In this second group, need for psychiatric treatment may be overlooked even when it has become urgent. It is important to differentiate between the two groups.

The general practitioner will fairly often be consulted by a middle-aged patient with a history of vague pains and aches more or less well localized and of fairly recent onset who on physical examination will not yield any findings of organic illness which would explain the symptoms. It might be only after repeated visits that the patient will confide and mention to the physician his fear of having cancer. Once this fear is voiced and discussed, most patients will be able to accept reassurance as to the absence of such illness and the symptoms will disappear with the medication prescribed, usually a mild sedative or analgesic.

By and large the physician does not discourage his patients from seeking consultation on such an "imaginary" ailment, mainly because he recognizes the tremendous importance of early detection of cancer. On the contrary, most physicians will encourage their patients to seek them out whenever they feel that something might be seriously wrong with their bodies. At the same time, the physician also expects his patient to be able to accept his considered opinion that nothing is seriously wrong and that there is no evidence of cancer. Most patients can do that, but some cannot.

As far as the patient is concerned who comes to the general practitioner with "cancerophobia" and is able to accept reassurance as to the absence of cancer, the following psychodynamic considerations seem to apply: For some extraneous reason not connected with his physical health, the patient experiences a sudden rise in anxiety and feels threatened and insecure. As a result he becomes overly concerned with his body and body functions. Some vague pain or sensation which under ordinary circumstances would probably have been disregarded altogether now becomes the focus of anxiety and increased tensions which in turn set up a vicious circle by increasing the sensitivity and perceptiveness in that area. Once this circle of anxiety/organic symptoms is set in motion and as the pain and dis-

---

Assistant Professor, Department of Psychiatry, University of Wisconsin.

comfort loom bigger and bigger in the mind of the patient, the fear of the unknown replaces or overshadows completely the original anxieties. This fear is expressed in whatever socially or culturally acceptable form of physical illness is prevalent at the time, currently, the fear of cancer. (Not so long ago it was the fear of tuberculosis.) In consulting his physician, the patient can get reassurance and regain his old feeling of security without the original anxieties ever coming to the surface.

There are other patients who will often present themselves initially with very similar complaints to those described but will be unable to accept reassurance. Such a patient's symptoms do not respond to such medication as mild sedatives, analgesics, or "tranquilizers." He will return repeatedly with the same complaint and show increasing anxiety and desperation over the physician's inability to help him. And, as his complaints intensify, it will finally be apparent that his fear, his belief that he must have cancer, is very deeply seated indeed and not accessible to correction by such measures as reassurance. At this point it becomes extremely important to recognize that the simple diagnosis of cancerophobia is no longer applicable. To be described in these terms, the fear of cancer has to be recognized by the patient as being irrational and it has to be accessible to correction by a new experience, namely, physical examination and perhaps some of the usual laboratory tests, followed by reassurance that all is well. If the fear persists, it merits the designation of "delusion," a fixed idea which corresponds in its emotional direction to the affect of the patient and which is not accessible to correction as long as the emotional condition persists which really gave rise to it in the first place.[1]

The differentiation between cancerophobia and the delusion about having cancer is not merely a semantic exercise but has great practical importance. The delusion usually is a symptom of a very serious underlying condition. If the physician does not recognize it, he will probably lose his patient, either to another physician or because of suicide.[2] But once he is alerted to the importance of the presenting symptom and its implications, the physician will easily discover a number of other symptoms which the patient has either not mentioned at all or which he has presented simply as difficulties resulting from the chief complaint, his fear of having cancer. He will probably find the patient suffering from insomnia with early morning waking, loss of interest in his usual pursuits and in his environment, loss of appetite with some recent weight loss, disturbance of concentration, and increased emotional lability with depressive affect. The general practitioner might get this history from a new patient who is consulting him after leaving his former family physician who "couldn't give me satisfaction, didn't help my condition." Statements such as these, on closer inquiry, will be found to mean that his physician could not find any organic illness which would explain the patient's concern and anxieties. Sooner or later such a patient might be hospitalized for further studies, usually with the same negative result as to finding of "organic" illness.

In these cases the correct diagnosis is usually one of a severe depressive reaction, especially if the patient is in the age group 45 or over. In younger patients a similar clinical picture will usually be presented in more bizarre language and be less fixed to any one organ, moving from one organ system to another; the possibility of a schizophrenic reaction should then certainly be seriously considered.[3] At any rate, the presence of a delusion of having cancer merits serious attention by the physician, and a psychiatric consultation is usually indicated.

Report of Cases

Case 1.—A 60-year-old married man was referred to the hospital with the chief complaint of backache. The backache was of fairly long standing but had become rapidly worse during the previous months to the point where the patient had to interrupt work about two months prior to admission. He had consulted an osteopath, a chiropractor, and several physicians. He had been hospitalized twice in the local hospital, many x-rays had been taken, and different prescriptions had been given—all to no avail. The backache persisted and he was unable to return to his work. The diagnosis so far had been given as moderate arthritis of the spine and mild generalized arteriosclerosis.

When I saw the patient first, he was agitated, restless, and depressed and expressed his conviction that he must have cancer of the spine. Some suicidal preoccupations could be elicited. Diagnostically, he presented the clinical picture of an agitated depressive reaction, but there was also evidence of a clearly defined though not very gross brain deficit, although the patient himself at first denied any impairment of memory. The key problem was soon clarified as being that this man experienced with advancing age some deterioration of his mental capacities of which he was aware but which he denied. In addition there was increased demand and pressure at work resulting from certain changes in his employment. The combination of these two factors, namely, the mild organic brain syndrome associated with general arteriosclerosis on the one hand and the increased demands in his work situation on the other hand, really placed the patient in a "situation without issue." His reaction was a feeling of helplessness and hopelessness leading to an increasing withdrawal from social contacts and a rising preoccupation with body functions and body feeling, resulting finally in a progressive exaggeration of the mild back pain which had been present but not disturbing him much over the last few years. He developed the conviction that he must have cancer of the spine, and no amount of reassurance given could shake this conviction. His depressive mood, his agitation, his insomnia, and his loss of weight were all very plainly there to be seen and evaluated yet were not understood in their proper meaning because they were simply thought to be the "natural" reaction of a man who fears that he has cancer.

At the time of this patient's transfer to the psychiatric ward of a general hospital the depressive reaction had achieved such magnitude that he was no longer accessible to a psychotherapeutic approach and he was given a course of electroconvulsive treatments. He responded very well, and with the lifting of the depressive mood the back pain and the cancerophobia also disappeared. The task remained to help this man with further planning, to help him to a change of jobs which would permit him to exercise old overlearned skills which had not been affected by the slowly beginning mental (arteriosclerotic) deterioration and which would afford him gratification from areas of competence so that he could reestablish his self-concept at a comfortable level.

Case 2.—A housewife, aged 54, was admitted to the medical service of the hospital with the chief complaint of abdominal pain. The description of the pain was extremely vague and of changing location. She also complained about yellow stools and yellow urine, and there had been a 16-lb. (7.3-kg.) weight loss during the year prior to admission, apparently the result of marked anorexia. The patient had been seen by a number of doctors and had undergone a hemorrhoidectomy about six months prior to admission. Since then she had repeatedly voiced her conviction that she was suffering from cancer, which she thought was evident from the color and shape of her feces, from her weight loss, and from a general feeling that her muscles were just wasting away. No amount of medical attention could shake these beliefs; she changed physicians repeatedly in an attempt to gain help, but at the time of her admission to the psychiatric service she had reached the point where she felt that physicians could not be trusted any longer. She thought that there was a conspiracy of silence between them not to tell her the truth, namely, that she was suffering from cancer of the colon. Repeated physical examination and complete laboratory and x-ray studies had consistently shown her to be in good physical condition.

Psychiatric interviews revealed that the patient's preoccupation with her bowel function followed the death of her brother, who died from cancer of the colon. She soon thought she too had similar symptoms, and this led her to seek medical advice. Her complaints first led to a hemorrhoidectomy, but a short time after her discharge from the hospital she experienced the death of her mother, which further contributed to her depressive reaction. Unfortunately her emotional condition was not recognized by her physicians, who continued to treat her for the presenting symptom, abdominal pain. The referring physician mentioned that the patient had developed cancerophobia after the hemorrhoidectomy, yet he continued to treat her medically for her abdominal complaints, offering reassurance as to the absence of malignancy. Characteristically this referral to the hospital was made to the medical service, and psychiatric consultation was not requested at any time.

When I saw the patient first there could be no doubt about the presence of a depressive reaction which had reached psychotic magnitude. She responded well to a course of electroconvulsive treatments and has remained well for a two-year follow-up period.

Summary

The fear of having cancer is a fairly frequent phenomenon that brings patients to consult their doctor. There are two types of patients who present this symptom without having cancer: those who can accept reassurance that all is well and those who cannot and become increasingly anxious. This reflects a difference between cancerophobia and the delusion of having cancer. The latter is interpreted as a symptom of an underlying severe emotional disturbance which merits psychiatric consultation.

FINGERTIP HYPERESTHESIA

SOLITARY SIGN OF NEW OCCUPATIONAL DERMATOSIS DUE TO SILICA HAIR CURLERS

Walter B. Shelley, M.D.
and
Donald M. Pillsbury, M.D., Philadelphia

Microfragments of silica embedded in the outer layers of the skin were detected by dark-field microscopy of superficial skin biopsies. Transfer from silicon hair curlers handled in the patient's occupation as a hairdresser was facilitated by the fact that daily contacts with alkaline hair sets and waving solutions served to soften the stratum corneum and epidermis. Precise and exactly localizable micropoints of hyperesthesia were identified. Cure was provided by a superficial razor shave biopsy. Prophylaxis must center on avoidance of the new silica rollers.

We wish to report a distinctive new entity seen as an occupational disease in a hairdresser. The solitary clinical finding was persistent punctate hyperesthesia of the fingertips. After considerable diagnostic study the hyperesthesia was demonstrated to be due to tiny particles of silica which became embedded in the epidermis, impinging on the sensory nerve endings. The recent widespread use of silica or sand-coated hair curlers suggests that such an *invisible foreign-body hyperesthesia* may become common among beauticians unless efforts are taken to eliminate this new occupational hazard. Furthermore, failure to recognize the entity may subject patients to extensive medical investigations which otherwise could be eliminated once the occupational nature of the problem is recognized.

Report of a Case

The patient, referred to us by Dr. Meyer Naide, was a 40-year-old woman in good health who first noted a marked sensitivity of the fingertips to light touch. This began in September, 1958, on the lateral side of the tip of the right fourth finger. Shortly thereafter the medial tips of both thumbs were similarly affected. Eventually all of the fingertips became involved to a greater or lesser degree. Pain and inflammatory changes were absent, but exquisite tenderness to touch continued. No other sensory changes had been noted by the patient.

She gave a history of a hysterectomy, an appendectomy, and the surgical removal of a sebaceous cyst, as well as the surgical repair of a rectal fissure. She denied any personal or familial history of diabetes mellitus, skin disease, neurological disease, or Raynaud's disease. She did claim to be "allergic" to penicillin. For many years she had been employed as a hairdresser, and she gave no history of new contactants at work or home. Born in Texas, she had lived in Philadelphia for the past 16 years. She stated that she did not drink alcoholic beverages but that she did smoke a pack of cigarettes a day.

Prior to our studies she had been seen by a number of physicians who had considered a variety of presumptive diagnoses, including glomangioma (glomus tumor), peripheral neuritis, peripheral vascular disease, erythredema polyneuropathy (acrodynia), cervical rib syndrome, hysteria, spinal cord lesion, malingering, syringomyelia, and tumor.

During a hospitalization the following studies and results were reported: hemoglobin level 15.1 Gm.%; white blood cell count 7,800 per cubic millimeter, with 74% neutrophils, 23% lymphocytes, 2% monocytes, and 1% eosinophils; hematocrit value 48%; urinalysis, occasional hyaline and finely granular casts and 4+ protein; serum Kolmer and Kline tests, nonreactive; blood urea nitrogen level 10 mg.%; sugar level 83 mg.%; calcium level 9.1 mg.%; phosphorus level 2.7 mg.%; protein level 5.8 Gm.%, with albumin 3.3 and globulin 2.5; and x-rays of chest, hands, and cervical spine normal.

General physical examination was noncontributory. Neurological consultation revealed no objective evidence of disease. Results of vascular studies were likewise normal. The fingers were warm and had equal surface temperatures. Radial and ulnar pulses were normal, as were oscillometric readings. Studies on her reactive hyperemia and also vasodilatation tests disclosed a normal circulation in the fingers. Treatment with a variety of local anesthetic and steroid creams was unavailing. Likewise, a short course of systemic prednisolone (Meticortelone) therapy was reported to be without effect.

We first saw the patient in consultation at the end of November, 1958. At that time she was unable to work because of the incapacitating hyperesthesia of the fingertips. Gross examination revealed normal skin. Sweating patterns on the hands were also entirely normal. However, under Zeiss stereoscopic surface microscopy (80 ×), fine fissures could be seen in the stratum corneum of the thumbtips. Microsensory testing revealed these to reflect the exact areas of tenderness.

From the Department of Dermatology, University of Pennsylvania School of Medicine.

Specifically questioning the patient regarding abrasive materials, we were then able to elicit the fact that three months prior, coincident with the appearance of her fingertip problem, she had first begun to use a new "silicon hair curler." She described handling as many as 450 of these a day, six days a week, for nearly three months. These silicon hair curlers were covered with a fine granular material, presumably sand glued to a cardboard roller. In the course of use, the curlers lost their rough surface and, once smooth, had to be discarded. Prior to the exclusive use of these new curlers the patient had been using regular rubber and plastic curlers. In addition to the contact with the silicon curlers, the patient had considerable daily "wet work" with alkaline hair sets and waving solutions. It became apparent that tiny invisible fragments of the silica material from the curlers might have become embedded in the softened macerated stratum corneum and epidermis as a result of constant use of the curlers.

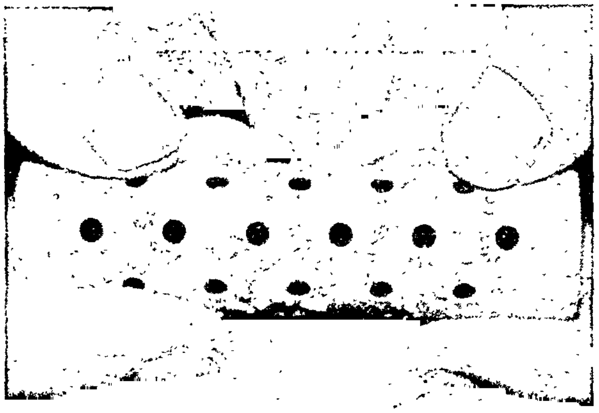

Fig. 1.—View of silica hair curler, showing surface rough with irregularly glued grains of silica. As curler is twirled, points of maximal friction are at medial tips of thumbs and tips of fourth fingers.

Many observations and tests confirmed this. First, the gross hyperesthetic areas proved to be exact points (fig. 1) of maximal friction between skin and curler.

Second, the curler particles, measuring 0.5-1.0 mm., were found to fragment easily into microparticles (5-100μ). Spectroscopic examination revealed them to be essentially silica. Silicon was the major component, with less than 0.1% each of aluminum, iron, calcium, magnesium, titanium, and copper present. The following elements were checked, but not found: chromium, boron, cobalt, cadmium, lead, columbium, manganese, gallium, nickel, germanium, silver, gold, sodium, molybdenum, zinc, platinum, antimony, strontium, arsenic, tellurium, barium, tungsten, beryllium, vanadium, bismuth, and zirconium.

Third, the hyperesthesia could be shown to be composed of many micropoints of hypersensitivity. Such study was done with use of a micropoint (30μ) stimulus. The points of pain on pressure were precise and exactly localizable. All of the discernible microfissures were hypersensitive, but many hypersensitive points could be found where the overlying skin was entirely normal at 80 ×. All of the testing was done under high-power stereoscopic visualization with a micropoint stimulator and in such a way that the patient was unaware of the point of stimulus. Significantly, the points remained constant in site and attempts to secure varying sensory responses from the patient met with failure. The exact number of hypersensitive points was high. For example, careful mapping of the right fourth fingertip revealed 22 distinct puncta. The points were remarkably discrete, so that testing the skin from 100μ away gave a negative report. Finally, the hyperesthesia was always appreciably less when the stratum corneum was dry.

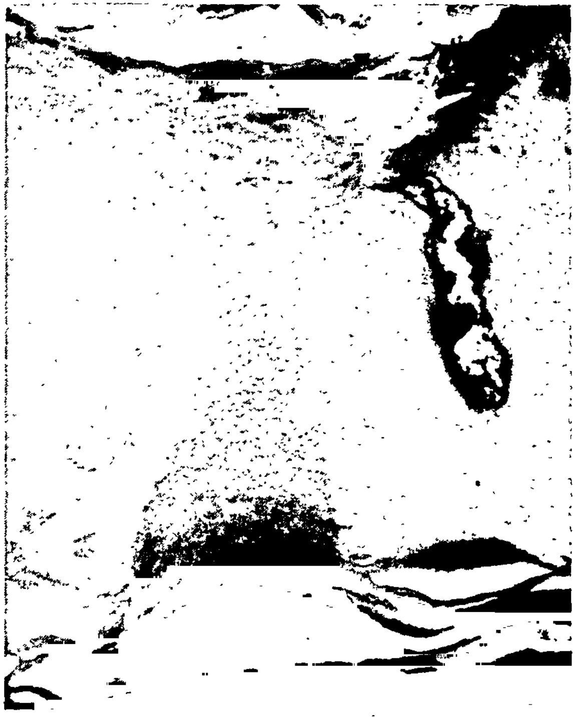

Fig. 2.—View of epidermal biopsy from tip of patient's finger, showing site of entrance of irregular particles of sand from hair curler. Part of foreign material has fallen out during sectioning, but shape of gross particle can be seen as lacuna in stratum corneum (210 ×).

Fourth, superficial skin biopsies were obtained (December, 1958) and study of complete serial sections revealed many black foreign bodies in the stratum corneum (fig. 2) and a lesser number in the lower epidermis. An occasional particle was seen in the upper papillary layer of the dermis. In some specimens ragged lacunae could be seen which were presumed to be the site of the silica prior to sectioning. It was possible to see the points of entry of some of the larger particles. Some pressed directly on the Meissner tactile corpuscle of the dermal papilla (fig. 3). Significantly, some of the histological particles could easily be dismissed as "dirt on the slide or stain precipitate" by the casual examiner. Only by being alert to the possible appearance of these grains and by using serial sections was it possible to track down the offending mechanical agent. Conclusive evidence of the identity of the intraepidermal particles and the silica of the rollers was provided by darkfield microscopy. Under this form of lighting the particles no longer were dark but became refractile with minute concentric ring formations seen under photography in both the tissue foreign material and the silica fragments.

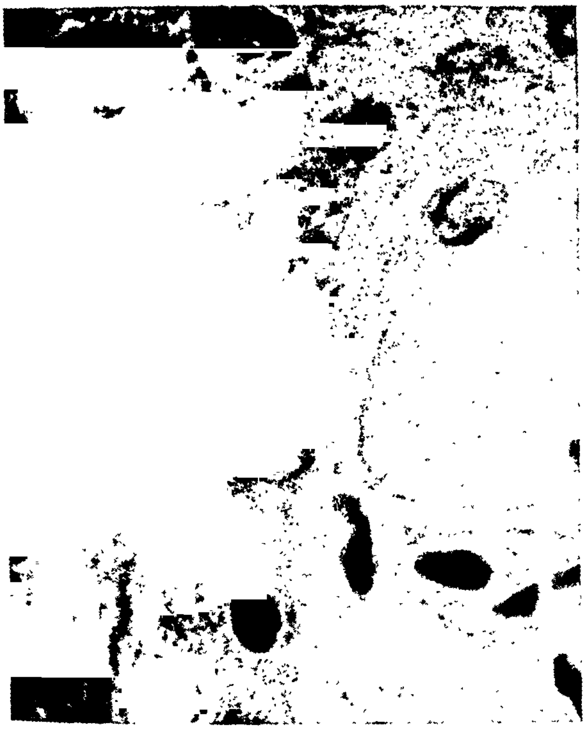

Fig. 3.—View of irregular black silica particle in epidermal rete peg, impinging on Meissner's corpuscle in dermal papilla (right). Nerves are not stained, but typical collagen whorl of Meissner's corpuscle can be seen (1,360 ×).

Once the cause had been detected, it was possible to offer a cure. The superficial location of the material has made it possible to remove the cause of the hyperesthesia by a superficial razor shave biopsy.[1] This requires no sutures and heals well. In this patient the operation was followed by temporary numbness and hyperesthesia. In all, the operation was performed on five of the fingertips.

Comment

We have described a new occupational hazard for hairdressers, which to our knowledge has not been previously reported.[2] Clinically occult, the problem presents itself as a punctate, highly localizable hyperesthesia of the fingertips. In some instances under high magnification the skin surface may reveal tiny fissures, but in others the skin may be entirely normal. It thus becomes an "invisible occupational dermatosis" readily recognized only after securing the history of contact with silica hair curlers. Skin biopsy will confirm the diagnosis of revealing microscopic intraepidermal silica particles at the points of fingertip tenderness. It can be seen that the silica fragments will penetrate the macerated skin of persons who have their hands in various rinses, sets, and wave solutions. Furthermore, the degree of exposure will in part be a determinant. *We have no knowledge of the factor of individual* susceptibility. Differential diagnosis will include neurological or peripheral-vascular disorders. Indeed, the patient may never have been seen by a dermatologist because of the absence of objective cutaneous signs. Glomangioma remains the condition which will most likely simulate this entity.

Prophylaxis must center on the avoidance of these new silica rollers. The degree of hazard cannot be accurately assessed at present, but it appears probable that repeated daily contacts with the silica roller might produce symptoms in a high proportion of professional beauticians and make avoidance of the device mandatory.

Active treatment consists in removal of the foreign material. Generally, it would appear this can best be done by a superficial razor shaving of the top layer of skin. Local as well as systemic medical treatment would seem to be ineffective. However, if the particles are all intraepidermal, it might be anticipated that over a period of months spon*taneous shedding and cure could occur.*

Summary

A new, invisible occupational dermatosis, clinically mimicking glomangioma, occurred in a hairdresser. It consisted of punctate hypersensitivity of the fingertips resulting from entrance of foreign particles of silica. These silica particles rubbed off a new type of hair curler and became embedded in the macerated outer layer of skin. Microsurgical treatment was successful in the case reported.

AUTOMATIC DETECTION AND RECORDING OF CARDIAC ARRHYTHMIAS

Edgar Haber, M.D., Boston

The cardiac monitor here described is a portable instrument used in connection with a standard electrocardiograph. From this source the monitor receives impulses which are amplified and interpreted, actuate the recording mechanism, cause an alarm to sound, and can, optionally, start up an electrical cardiac stimulator. Five cases illustrate its operation in patients with episodes of ventricular asystole, asymptomatic changes in intraventricular conduction, a paroxysm of bigeminal rhythm, an episode of extreme nodal bradycardia, and bouts of asymptomatic paroxysmal ventricular tachycardia. In a sixth patient the instrument recorded a sudden change from a sinus rhythm at 65 to a nodal rhythm at 80 beats per minute. This sort of continuous monitoring has evident advantages over intermittent observation.

Within recent years, much attention has been given to the detection of cardiac arrest and its prompt treatment. A device has been described which will sound an alarm in the event of asystole and even automatically begin electrical stimulation of the heart.[1] However, the occurrence of cardiac arrest or ventricular fibrillation may simply represent the end-point of a long chain of unfavorable events, which may then prove irreversible. Other arrhythmias, which often portend the appearance of asystole or ventricular fibrillation, require as prompt attention and are in most instances more readily treated.

During cardiac surgery changes from normal rhythm often precede the terminal arrhythmia.[2] It is well known that Stokes-Adams episodes may be the result not only of transient asystole but also of ventricular tachycardia or fibrillation.[3] In digitalis intoxication or myocardial infarction either abnormal ventricular or supraventricular rhythms may shortly precede fatal arrhythmias. In each of these situations the prompt application of prophylactic measures and appropriate treatment may be lifesaving. Delay is often fatal and every moment of forewarning is valuable.

In addition to the changes of rhythm of serious prognostic significance, there occur annoying paroxysmal supraventricular arrhythmias of brief duration which escape identification and consequently specific treatment. More often than not, before the electrocardiograph can be found and put into operation, the arrhythmia has ceased spontaneously.

Intermittent observation of a patient by nurse or anesthetist will often result in failure to detect the presence of a transient arrhythmia or the time of onset of a more persistent one. On occasion, changes in rhythm may occur which are not readily detectable by palpation or auscultation (as idioventricular rhythms at relatively slow rates) but which may nevertheless lead to rapid circulatory collapse. Stationing a trained observer by a continuously recording electrocardiograph or oscilloscope is certainly an impractical solution in most instances.

This paper describes a cardiac monitor which is capable of detecting most significant changes in rhythm and rate, sounding an alarm, recording an electrocardiographic tracing at the time of onset of the arrhythmia, and, in some instances, administering predetermined treatment prior to the arrival of the physician.

Apparatus and Technique

The cardiac monitor is a compact, portable, single-channel, direct-writing, electronic instrument (about the size of a large table-model radio), simply built and used in conjunction with a standard electrocardiograph. The monitor receives impulses from the amplifiers of the cardiograph (fig. 1). On the basis of interpretation of these impulses it controls the motor and stylus of the cardiograph, a loud-speaker which produces an audible sound with each heartbeat, a signal device which sounds when an arrhythmia is detected, and optionally an electrical cardiac stimulator or electric valves controlling the infusion of appropriate drugs. The electrodes are taped to the patient's trunk and a long cable is used to allow for freedom of movement. Special circuits prevent patient movement and poor or broken connections from activating the device so that patients may get in and out of bed with ease. The monitor may be set to detect tachycardias (above 50 to 200 beats per minute), bradycardias (below 2 to 60 beats per minute), or the occurrence of bundle-branch block (increase in duration of QRS complex). When an arrhythmia occurs, a distinctive signal sounds (e. g., bell for bradycardia, buzzer for tachycardia) and a brief cardiographic record is written. The signal does not cease (unless turned off manually) until normal rhythm is restored, but the duration of the cardiographic record is preset and independent of the duration of the

Read in part before the New England Cardiovascular Society, March 10, 1958.

arrhythmia. At the onset of the next disturbance, the signal sounds again and another electrocardiographic strip is written.

Not only will arrhythmias be detected but, once the diagnosis has been established in a patient with multiple episodes of the same disturbance, therapeutic measures may be automatically initiated before the arrival of the physician. For example, in the event of asystole, but not any other arrhythmia, a stimulator circuit can be activated to apply rhythmic pulses to the chest wall, or in the event of tachycardia responding to procainamide, an infusion of this drug can be started by electrical valves controlled by the monitor. As soon as the rate returns to within the desired range, the valves stop the infusion, only to restart it should the abnormality recur. Were an arrhythmia other than tachycardia to occur, the monitor in this instance would perform its diagnostic services only and refrain from injudiciously applying therapy.

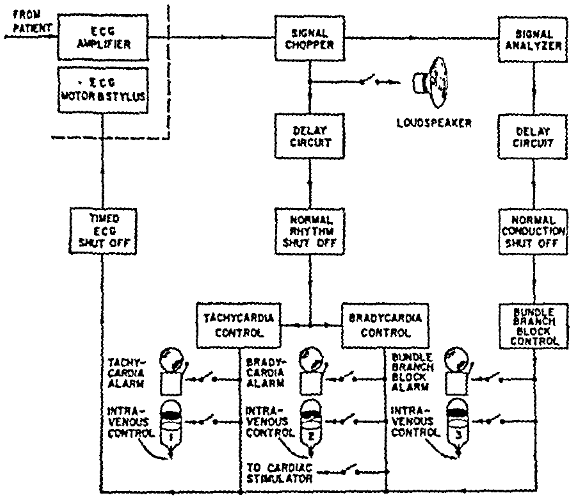

Fig. 1.—Block diagram of monitor circuits. Patient is attached to electrocardiograph. QRS pulses from the ECG amplifier are modified by signal chopper and signal analyzer so that only essential changes in configuration affect subsequent circuits and artifact potentials are eliminated. Loud-speaker may sound with each cardiac contraction. Intervals between pulses are measured in tachycardia control and bradycardia control circuits, while width of pulse is measured in bundle-branch block control circuit. Delay circuits, by averaging pulse rate and QRS duration, prevent transient disturbances from having effect, while normal rhythm and normal conduction shut-off circuits inactivate device on restoration of rhythm to prior state. Each type of arrhythmia control circuit activates different type of alarm and independent intravenous control. Bradycardia control may optionally turn on cardiac stimulator. Each arrhythmia control circuit can turn on ECG motor and stylus, duration of tracing being determined by timed ECG shut-off circuit.

Report of Cases

Case 1.—A 65-year-old woman was admitted to the Massachusetts General Hospital, Boston, on March 10, 1958, because of congestive heart failure. There was no history of syncopal episodes. Initial electrocardiogram showed normal sinus rhythm and right bundle-branch block. After being treated with digitalis and meralluride (Mercuhydrin), she had a diuresis with a 10-lb. (4.5-kg.) weight loss. Subsequent electrocardiogram showed 2:1 and 3:1 heart block. Because of the occurrence of a convulsive episode, the cardiac monitor was used. On two occasions the monitor's alarm warned of ventricular asystole (fig. 2*A*) and electrical stimulation was begun with effective results (fig. 2*B*). On another occasion a ventricular rhythm at a rate of 100 triggered the monitor (fig. 2*C*) and led to manual slowing of an intravenous infusion of epinephrine.

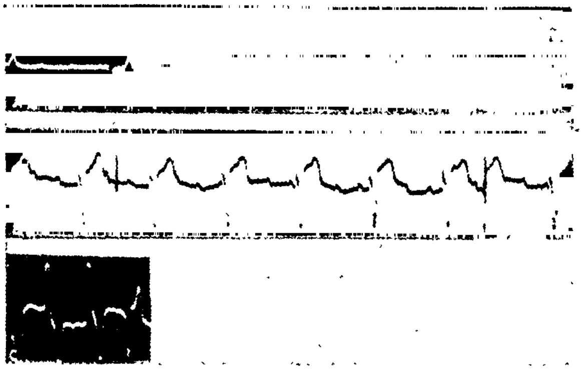

Fig. 2 (case 1).—Tracings taken automatically through monitor circuits. *A*, 3:1 atrioventricular block followed by ventricular asystole with continued atrial activity. *B*, ventricular systole in response to electrical stimulation. *C*, spontaneous ventricular tachycardia.

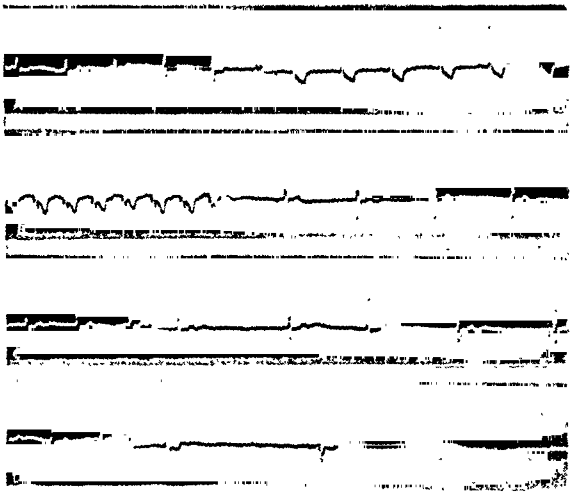

Fig. 3 (case 2).—Tracings taken automatically through monitor circuits. *A, sinus rhythm at 80 beats per minute.* Second part of tracing represents change in conduction pathway. *B*, nodal tachycardia at 120 changing to sinus rhythm at 60 beats per minute. *C*, sinus arrest with an irregular nodal bradycardia, following a faster nodal rhythm. *D*, sinus rhythm, followed by sinus arrest and then ventricular asystole.

Case 2.—A 76-year-old woman entered the hospital on April 17, 1958, because of congestive heart failure related to coronary artery disease and aortic stenosis. There was no history suggestive of paroxysmal arrhythmias. Initial electrocardiogram showed normal sinus rhythm. The patient was at first selected as a control for study of the monitor's stability. However, during a 24-hour period the monitor recorded a paroxysmal change in intraventricular conduction (fig. 3A) without change in rate, several nodal tachycardias (fig. 3*B*), a nodal bradycardia (fig. 3*C*), and sinus arrest with occasional nodal escape beats (fig. 3*D*). None of these changes in rhythm was symptomatic.

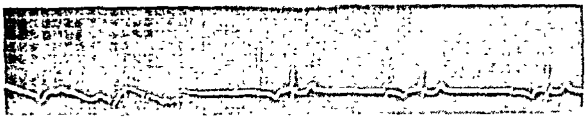

Fig. 4 (case 3).—Tracings taken automatically through *monitor circuits. Sinus rhythm is followed by bigeminal* rhythm.

CASE 3.—A 79-year-old man was hospitalized on May 11, 1958, because of symptoms suggestive of intermittent cerebral vascular insufficiency. While in the hospital he complained of brief bouts of palpitations which never occurred in the presence of an observer. An electrocardiogram was within normal limits. The cardiac monitor was attached and after several hours a record of a paroxysmal episode of bigeminal rhythm was taken (fig. 4).

CASE 4.—A 66-year-old woman was admitted on May 12, 1958, because of acute bacterial endocarditis. Initial electrocardiogram (fig. 5A) showed atrial fibrillation at an average ventricular rate of 50 beats per minute. Several hours after the monitor was instituted, the alarm sounded and the patient was found in the midst of a convulsive seizure. An electrocardiogram taken by the monitor revealed extreme nodal bradycardia (fig. 5*B*). Administration of epinephrine resulted in an increase in rate. Over the next 24 hours regular nodal rhythm at 80 beats per minute (fig. 5*C*) and a nodal tachycardia at 130 beats per minute (fig. 5*D*) were recorded by the monitor but were unassociated with symptoms.

Fig. 5 (case 4).—Tracings taken automatically through monitor circuits. *A*, atrial fibrillation, admission rhythm. *B*, extreme bradycardia. *C*, nodal rhythm. *D*, nodal tachycardia.

CASE 5.—A 58-year-old woman was admitted to the hospital on May 16, 1958, because of intermittent periods of faintness and vertigo. The initial electrocardiogram showed sinus rhythm at a rate of 65 beats per minute. Within an hour the patient's heartbeat had spontaneously converted to a nodal rhythm at a rate of 80 beats per minute, which was recorded by the monitor (fig. 6).

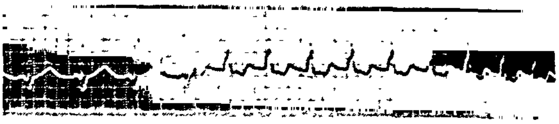

Fig. 6 (case 5).—Tracings taken automatically through *monitor circuits. Sinus rhythm at 80 beats per minute* changing to nodal rhythm at 90 beats per minute, with marked change in conduction pathway.

CASE 6.—A 61-year-old woman was admitted on June 3, 1958, with a history of complete heart block of many years' duration and occasional episodes interpreted as Stokes-Adams syncope. The electrocardiogram showed that rhythm on admission (fig. 7A) was complete atrioventricular dissociation. In the course of a 24-hour period several bouts of paroxysmal ventricular tachycardia were recorded by the monitor; none of these was symptomatic (fig. 7*B*).

Comment

These six cases illustrate that the monitor is capable of detecting not only tachycardias (cases 2, 4, and 6), bradycardias, or asystole (cases 1, 2, and 4) but also changes in the configuration of the QRS complex without significant change in rate (cases 1, 2, 3, and 5).

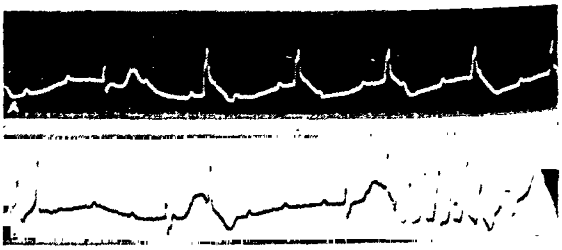

Fig. 7 (case 6).—Tracings taken automatically through monitor circuits. *A*, admission rhythm, third-degree heart block. *B*, runs of paroxysmal ventricular tachycardia.

Aside from evident application in the operating room or in instances of known Stokes-Adams syncope, it may be used to advantage in patients who complain of paroxysmal palpitations or those who are likely to develop dangerous arrhythmias. In an already present arrhythmia under treatment, the device may be used in monitoring the time of conversion to normal rhythm so that medication need not be continued longer than necessary.

Because of the stability of the circuit, it may be used with relative patient comfort for long periods. In one instance the monitor remained in place continuously for three days, during which time several moves from chair to bed or commode were made without accidental activation of the device.

Summary

A cardiac monitor used during the occurrence of significant cardiac arrhythmia will sound an alarm, cause an electrocardiograph record to be taken, stimulate the heart electrically during asystole, and cause pharmacological agents to be administered during appropriate changes in rhythm. It is believed that this device will be of value in warning of the occurrence, recording the nature, and in some instances beginning treatment of paroxysmal cardiac arrhythmias.

SIMPLIFIED TECHNIQUE FOR SEPARATION OF CANCER CELLS FROM BLOOD

LeRoy Long, M.D., Stuart Roberts, M.D., Ruth McGrath, B.S.
and
Elizabeth McGrew, M.D., Chicago

The Malmgren method for the isolation of cancer cells from whole blood was simplified by substituting a centrifuge process for the filtration method of collecting cells for examination. The new method, which can be carried out in the average laboratory, produces slides of a quality comparable to those from other techniques with regard to preservation of tumor cell structure, minimal cell clumping on the slide, and adequate red cell removal from the final preparation. The Papanicolaou preparation of the slide distinguishes the malignant cell when read by a competent cytologist.

Cancer cells are often found in the blood stream of patients with malignant diseases, but only recently have laboratory techniques enabled more complete study of this phenomenon. Engell[1] reopened this field of investigation; he pointed out that malignant cells in the blood were first identified almost 100 years ago, but since that time only sporadic reports had appeared in the literature. In the course of these new studies, certain inconsistencies have arisen which require numerous observations of patients and the concurrent examination of their blood for the presence or absence of tumor cells. Because of the technical difficulties in the separation methods currently in use, requiring skilled techinicians and expensive equipment, many persons have been loath to attempt such studies. For this reason a modification of the technique first described by Malmgren and co-workers[2] has been developed by us which stresses simplicity, the use of ordinary laboratory equipment, and, insofar as possible, maintenance of the physiological state.

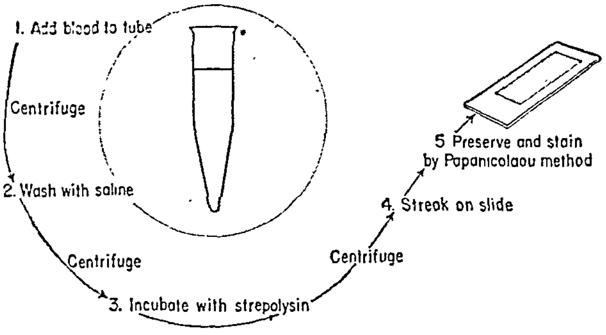
Review of Previous Methods

The method utilized by Engell requires the use of 2 to 5 ml. of heparinized blood from which the cellular elements are collected after centrifugation. These cells are treated with 1% saponin solution to lyse red blood cells; the remaining white blood cells and tumor cells are then coagulated with citrated plasma. These cellular "buttons" are then treated according to ordinary histological technique, mounted in paraffin, cut into serial sections, and stained with Hansen's hematoxylin and 1% aqueous eosin. The principle of this technique is hemolysis. Although this is the classic approach to the problem

---

From the departments of surgery and pathology, University of Illinois Hospitals.

of isolation of malignant cells from the blood, the technical manipulations are considerable and the tumor cells may be damaged by the strong hemolyzing agent used.



*All samples are processed in the same 50 cc. centrifuge tube

Fig. 1.—Procedure of separation of cancer cells from blood.

A second method currently in use was developed by Sandberg and Moore.[3] This method relies on artificially accelerated sedimentation of red blood cells with bovine fibrinogen. The supernatant fluid is then centrifuged and the sedimented cells are smeared and stained with Wright's stain. The advantage of this method is simplicity, but the drawbacks make this method less acceptable than others. These disadvantages include lack of quantitation, loss of tumor cells which are carried down with the sedimented erythrocytes, and the further disadvantage that the 5-10% erythrocytes which remain form a red precipitate when stained by the Papanicolaou method.

Beginning work in July, 1956, Roberts and associates[4] developed still another method, which took advantage of the fact that tumor cells are usually lighter than the formed elements of blood. Once again heparinized blood (10 ml.) is used. Fibrinogen is added to speed sedimentation of the erythrocytes. The supernatant portion is then decanted and layered over 5 ml. of iso-osmotic albumin solution with a specific gravity intermediate between that of tumor cells and that of normal blood cells. This preparation is then centrifuged and the heavier leukocytes are spun to the bottom of the tube, while the tumor cells collect at the plasma-albumin interface. Aspiration of the cells at the interface is carried out, and they are streaked on glass slides, preserved, and stained by the Papanicolaou method. The cells which have passed through the plasma-albumin interface are similarly treated, since it was observed that many tumor cells approximated the weight of white blood cells and were found with these sedimented cells. The principal advantage of this method is that it is physiological. The cell nucleus and cytoplasm are well preserved. Its main disadvantage is that it is not quantitative. A specimen negative for tumor cells does not mean that cells are absent, since many tumor cells are lost in the initial sedimentation of erythrocytes.

The method developed by Malmgren and associates[2] is a combined enzymatic and filtration method. Each blood sample (20 ml.) is washed with saline solution to remove naturally occurring antistreptolysin. The sample is then treated with streptolysin O, which lyses the erythrocytes and the polymorphonuclear leukocytes. After this, the remaining lymphocytes and tumor cells are resuspended in saline solution and filtered through a fine (5 μ) filter. The filters are then stained and mounted on large glass slides for examination. Filtration requires the use of an apparatus for creating negative pressure. The most obvious advantage of this method is quantitation. The advocates of this method have shown 100% recovery of counted cells. Also, a human tumor established in tissue culture was added to a blood sample and reseparated by this method. It was then successfully reimplanted—thus demonstrating viability of the tumor cells.

In our hands, however, this method has presented several difficulties. Filtration is technically difficult and unpredictable. Some samples are easily filtered, while others require much time and many filter changes. Cells are often distorted in the interstices of the filter by the pressure required for filtration. Microscopically, the filters are "wavy," as

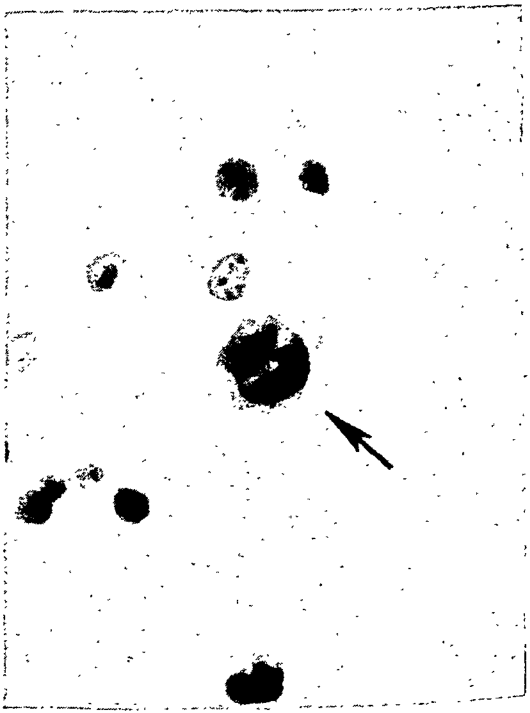


Fig.2.—Photomicrograph showing epidermoid carcinoma of penis (×1,100).

there is much background debris, making examination of the slides difficult. Also, the streptolysin O added to lyse the susceptible cells is hyperosmolar. (Made up with buffered solution, the streptolysin O solution is 790 milliosmols [mOsm.] per liter.)

Collection of Samples

As has been done in previous work reported from this laboratory, samples are collected from a variety of sources. These include peripheral (antecubital vein) catheter samples from large veins draining the general tumor area (inferior vena cava, axillary vein, etc.) and samples from veins directly draining the tumor (renal vein, mesenteric vein, etc.).

Method

We have modified Malmgren's method[2] with use of streptolysin O but rely on centrifugation rather than filtration to isolate the cancer cells; this is a very simple procedure and can be carried out without elaborate laboratory facilities; moreover, highly trained technicians are not required for this method. In the course of handling a blood sample there are only two procedures requiring the transfer of the sample from one container to another; these are the change of the blood sample from the syringe to a centrifuge tube and the transfer of the remaining tumor and white blood cells to glass slides. All steps concerning the actual lysis of red blood cells and polymorphonuclear leukocytes are carried out in the same 50-ml. conical centrifuge tube. This tube and the collecting syringes are siliconized with one of the standard materials generally available. A water bath, a centrifuge capable of 1,000 rpm, and ordinary glass microscope slides complete the necessary physical items. Reagents necessary are streptolysin O, isotonic sodium chloride solution, and distilled water. The general procedure is outlined in figure 1, and the detailed steps are given below.

1. Whole blood (10 ml.) is collected in a siliconized syringe and transferred to a 50-ml. siliconized conical centrifuge tube. These tubes contain 1 mg. of heparin in 0.1 ml. of solution.
2. The sample is centrifuged at 1,000 rpm for 20 minutes.
3. The plasma is decanted and 15 ml. of isotonic sodium chloride solution is added and mixed. The sample is recentrifuged for 20 minutes as before.
4. Once again the supernatant fluid is decanted and 15 ml. of saline solution is added, mixed, and centrifuged for 20 minutes. These washings are performed to remove the naturally occurring antistreptolysin.
5. Three 10-ml. vials of streptolysin O reagent (Difco Laboratories, Detroit) are prepared with use of 9 ml. of distilled water per vial. This must be used within 10 minutes. With most lots of streptolysin O this has resulted in a solution containing 280 mOsm. per liter.
6. The supernatant fluid of the last washing (step 4) is decanted, the three vials of streptolysin O are added, and the tube with its contents of enzyme and sedimented cells is incubated in a water bath at 39 C for 10 minutes. The contents are agitated gently during this incubation.
7. After incubation, the tube is centrifuged for 10 minutes at 1,000 rpm.
8. The supernatant fluid is decanted and 10 ml. of isotonic sodium chloride solution is added, the tube being once again centrifuged for 10 minutes at 1,000 rpm. This washing is to remove cell debris.
9. The supernatant fluid is decanted and the sediment placed on 12 ordinary glass slides and fixed immediately in ether-alcohol solution. These slides are stained by the Papanicolaou technique.[5]

Fig. 3.—Photomicrograph showing undifferentiated malignant retroperitoneal tumor (× 1,100).

10. Scanning is performed.
11. Confirmation by a trained cytologist is indicated.

Results

From a cytological standpoint the preparations obtained by this method have been satisfactory (fig. 2 and 3). There is a background of lymphocytes with a few polymorphonuclear leukocytes. It is sometimes possible to place the sediment on fewer than 12 slides, while at other times more will be necessary—the important consideration being a thin smear which makes the formidable process of scanning more reasonable. Most of the cells have been single, although some clumps have been identified. Some apparent tumor cells are stripped of their cytoplasm. We have also observed a number of large cells with a lobulated nucleus. These at first appear to be malignant cells, but further study has indicated that these are megakaryocytes—not malignant cells. Figure 4 shows such a cell which was identified in the peripheral blood of a patient with preinvasive carcinoma of the uterine cervix. Also shown in figure 4 is a megakaryocyte from the marrow of a "normal" patient for comparison. Both have been stained by the Papanicolaou method.

Viability of cells processed by this method has been shown by treating a suspension of Walker-256 carcinosarcoma cells by the above method and then injecting the suspension subcutaneously into rats. Four of 10 rats so injected developed tumor "takes." The usual "take" is 100%.

As stated previously, the method as described is extremely simple and can be carried out without elaborate equipment. In addition, the number of positive samples in 100 patients is about twice that revealed in our "interface" method. However, since the number of various types of cancer in this series is comparatively small, we are not reporting the actual percentage figures at this time.

Summary

A method of isolating cancer cells from the peripheral blood has been developed which is a modification of a method previously described but is much simpler. Our preliminary experience with it indicates that it compares favorably with other methods as far as quantitation is concerned. Its main advantage is that it is a technically easy method requiring only reagents and equipment available in most laboratories. The ever-present burden of careful scanning cannot be avoided, and the availability of a competent cytologist for positive identification of malignant cells is still essential.

840 S. Wood (12) (Dr. Long).

This study was aided by a grant from the U. S. Public Health Service.

INCIDENCE OF CHOLECYSTITIS AND OTHER DISEASES AMONG PIMA INDIANS OF SOUTHERN ARIZONA

Frank G. Hesse, M.D., Sacaton, Ariz.

Among 2,688 Pima Indians above the age of 15 years there were 125 hospital admissions for cholecystitis during a two-year period. During that same period only three cases of myocardial infarction were definitely diagnosed, no patient was treated for angina pectoris, and no case of peptic ulcer was reported. The average Pima Indian was found to consume 2,800 calories daily, and fats comprised 24% of the calories intake, with 87% being animal fat; lard was used almost exclusively as a cooking fat. Meat and vegetables were usually eaten about once a week. The role of diet in the etiology of the disease pattern among Pima Indians is consistent with current thinking as to the pathogenesis of degenerative heart disease.

It is well known to physicians working on Indian reservations in the Southwest that there is a relatively high incidence of gallbladder disease and low incidence of arteriosclerotic heart disease and peptic ulcer among southwestern Indian tribes. Lam,[1] in 1954, reported that gallbladder disease accounts for 3.6% of all hospital admissions and is the most frequent surgical condition encountered among the Sioux Indians. Gilbert,[2] in 1955, reviewed 10,267 Navaho Indian hospital admissions and reported 125 admissions for gallbladder disease and only 5 admissions in which coronary thrombosis was suspected (in none of these was it proved). No further reference to the incidence of these diseases is encountered in the medical literature. The present study reports the incidence of cholecystitis, arteriosclerotic heart disease, and peptic ulcer among the Pima Indians from the time (July, 1955) when the U. S. Public Health Service assumed responsibility for the medical care of the American Indian.

The Pima Indians live on a 372,000-acre reservation in the southern Arizona desert. They have accepted many of the white man's ways, especially modern medicine. Tribal medicine is almost extinct among the Pimas,[3] in contrast to many other southwestern tribes in which many diseases are treated by medicine men, making a statistical report almost impossible. The Pimas receive their medical care exclusively at the PHS Indian hospitals at Sacaton and Phoenix, Ariz. This report is an analysis of the records of these two hospitals over the two-year period from July, 1955, to June, 1957. The proportionate age groups of the tribe were obtained by estimates made from the 1950 U. S. census report.[4]

Findings

Gallbladder Disease.—There were 125 admissions for cholecystitis during this two-year period. These came from a population of 4,668,[4] of which 2,688 are above the age of 15 years and in the cholecystitis-susceptible age group. Out of every 100 Pima Indians above the age of 15, 2.3 were admitted yearly because of gallbladder disease. Admissions were for severe acute cholecystitis or for recurrent chronic cholecystitis with acute exacerbation of the disease. Patients with mild cases of cholecystitis were treated as outpatients and were not included in this study. The diagnoses were established on the basis of clinical history and physical examination and were supported by abnormal cholecystograms in 92% of the 125 admissions in this group.

Persons in all age groups between 20 and 70 years were approximately equally affected, with a preponderance in the sixth decade. There was a relatively high frequency in females below the age of 30. The incidence of cholecystitis is seven times higher in the female than the male (see table).

The incidence of diabetes in patients with cholecystitis was 12.5%. This compares to an incidence of 11.6% among all Pima Indian hospital admissions, suggesting that, while there is a relatively high incidence of diabetes among the Pimas, cholecystitis does not seem to be related to it. A history of cholecystitis in the immediate family was obtained in 34% of all patients with gallbladder disease. Cholecystectomy was performed in 74 patients during the two years, 18 of whom required exploration of the common duct.

Gallbladder carcinoma was found during operation in two Pima Indians. Of patients from all tribes admitted for cholecystitis to these two hospitals, 8 were found to have carcinoma of the gallbladder out of 273 admissions for cholecystitis—an incidence of 2.9%. Carcinoma of the gallbladder was the most common form of cancer seen in these two hospitals during the two years.

Arteriosclerotic Heart Disease.—There were three cases of myocardial infarction definitely diagnosed among Pima Indian admissions during the two years. One other patient had a clinical course suggestive of myocardial infarction but showed only a left bundle-branch block. Two other Pima Indians

---

From the U. S. Public Health Service Indian Hospital. Dr. Hesse is now with the Department of Surgery, State University of New York, Upstate Medical Center, Syracuse, N. Y.

were suspected of having myocardial infarction, though the history was difficult to obtain and the patients died aged 78 and 90, respectively, before an electrocardiogram was recorded.

No patient was treated for angina pectoris at the Sacaton hospital during the two years studied. During 1956, there were only 12 cases of coronary thrombosis diagnosed among the 23,000 southwestern Indians cared for by the Phoenix area office of the U. S. Public Health Service.

Peptic Ulcer.—There was no case of peptic ulcer reported among the Pima Indians in these two years. Among all tribes treated at the PHS Indian hospital at Phoenix, averaging 8,500 admissions annually, only 2 cases of duodenal ulcer, proved by x-ray, were found during the two-year period. Two other patients with a clinical history which suggested peptic ulcer had a normal gastrointestinal series. In 1956 five cases of peptic ulcer were diagnosed among the 23,000 southwestern Indians under the jurisdiction of the Phoenix area office.

Comment

The high incidence of gallbladder disease and the low incidence of arteriosclerotic heart disease and peptic ulcer in a relatively inbred tribe is difficult to explain on the basis of the currently suspected etiology of these diseases. The findings among the Pima Indians are consistent with the findings of Lam [1] among the Sioux Indians and Gilbert [2] among the Navaho tribe. The low incidence of peptic ulcer in an Indian tribe has not been previously reported.

Surgical facilities were inadequate in previous years to meet the demand for elective gallbladder operations, so that conservative treatment for cholecystitis was commonly prolonged. This may account partially for the high incidence of recurrent acute exacerbations of chronic cholecystitis and for the relative frequency of carcinoma of the gallbladder.

Other contributing factors may be the heavy body build with a tendency toward obesity found among Pima Indians. The role of diet in the etiology of this disease pattern is difficult to evaluate. A diet study of Pima Indians shows their basic food to consist of beans, tortillas, and coffee, with hot chili peppers a commonly used side dish. Meat and vegetables are usually eaten about once a week, due to lack of funds and lack of storage facilities for perishable foods. The average Pima Indian consumes 2,800 calories daily. This contains 105 Gm. of protein, of which only 16% originates from animal sources. Fats comprise 24% of the calorie intake, with 87% being animal fat. Most foods are fried in lard, which is used almost exclusively as a cooking fat.[5]

It is conceivable that the quantities of fried and spicy foods eaten regularly by Pima Indians may aggravate existing cholecystitis. The low incidence of coronary disease among these Indian groups in view of the relatively low-fat diet is consistent with the findings of Keys [6] in other population groups where a low fat intake was proportional to a low incidence of degenerative heart disease.

The rare occurrence of peptic ulcer among the Pimas and other Indian tribes may be due to the relatively low stress and noncompetitive nature of Indian communal life. It will be interesting to note any future changes in this disease pattern as the Indian is assimilated more into the competitive society of the United States.

Summary

A study of the incidence of gallbladder disease, arteriosclerotic heart disease, and peptic ulcer among the Pima Indians of southern Arizona was facilitated because the Pima is one of the few tribes that has completely accepted modern medicine; the statistical evaluation is, therefore, reasonably valid. In a population of 2,688 Pima Indians above the age of 15 years, 125 were admitted over a two-year period for gallbladder disease. The occurrence of cholecystitis is seven times more frequent in the female than in the male. Eight cases of carcinoma of the gallbladder were found among 273 admissions for gallbladder disease; this was the most common form of cancer seen. Three cases of myocardial infarction were diagnosed among Pima Indian admissions during the two years; no patient with angina pectoris was encountered. The low incidence of arteriosclerotic heart disease is interesting in that these Indians eat a relatively low-fat diet. No patients with peptic ulcer were seen during this same period.

Incidence of Cholecystitis According to Age and Size of Population Among Pima Indians, 1955-1957

Age, Yr.	Population	No. with Cholecystitis			Rate per 100 Population
		Male	Female	Total	
15-19	428	0	4	4	0.9
20-29	620	2	31	33	5.3
30-39	475	2	23	25	5.3
40-49	432	1	17	18	4.2
50-59	306	7	23	30	9.8
60-69	250	3	10	13	5.2
70+	177	0	2	2	1.1
Total	2,688	15	110	125	4.6

ELECTROSHOCK THERAPY AND TRANQUILIZING DRUGS

Stanley Lesse, M.D., New York

Electroshock therapy (EST) was used in 170 patients whose mental illness had not been ameliorated by intensive treatment with tranquilizing drugs. All of these patients were incapable of social or vocational activity before the EST and were rated 1 (lowest) on a 4-point scale. In another group of 131 patients the EST was given while the administration of tranquilizers was continued. Of the 170 patients, 117 (69%) had satisfactory results with EST, as measured by higher ratings on the scale. Simultaneous use of tranquilizers with EST did not reduce the number of EST treatments needed for good results, decrease apprehensiveness before treatments, or shorten the postconvulsive psychoses; neither did it increase the risks of EST. It did help in the management of agitated patients. It is therefore recommended only when specifically indicated in a given situation.

Determination of the relative merits and effectiveness of the tranquilizing drugs, as compared to electroshock therapy, in the management of certain types of psychiatric disorders is a controversial matter in present-day psychiatry. Some physicians maintain that electroshock therapy in combination with use of various tranquilizing drugs is more effective than electroshock therapy alone.[1] Others warn that this technique is fraught with danger.[2] The following observations are a summary of my experiences in this field during the past four years.

All the patients in these series were seen in private practice. They all received electroshock therapy in a hospital setting on either an inpatient or an outpatient basis, and they all had complete general and neurological examinations at the time of the initial visit. All patients over 35 years of age had electrocardiograms and chest x-rays prior to the electroconvulsive therapy (ECT). Laboratory studies were performed if indicated. In all but a few of the patients the ECT technique was to put the patient in a light sleep with intravenous administration of thiopental (Pentothal) sodium and then to administer succinylcholine (Anectine) chloride intravenously. The electric current was delivered with use of a standard unit, 50 seconds after the injection of succinylcholine.

Method of Evaluating Level of Improvement

The technique used in evaluating the level of improvement was the same as that explained by me in previous publications on various therapeutic methods.[3] It considers and attempts to quantify, whenever possible, both subjective and objective factors. The criteria used stress the patient's adaptation to routine responsibilities of everyday life in addition to the degree of symptomatic improvement. The degree of pride and pleasure derived from successful performance was also considered. This is a rather strict technique of evaluation and presupposes that the patient has been facing the routine responsibilities of everyday life. In detail, the factors evaluated were as follows:

Performance.—Vocational performance was considered (1) excellent if the patient held full-time employment, functioning efficiently without strain and taking great pride and pleasure from attainments; (2) good if he held full-time employment, functioning with greater effort than was necessary prior to illness and taking moderate pride and pleasure from attainments; (3) fair if he was employed intermittently, functioning with considerable difficulty and frequently absent with faulty performance at times and lack of pride and pleasure; and (4) poor if he was unable to perform at all.

Social performance (individual and group interpersonal relationships) was considered (1) excellent when his social performance was active and comfortable with a high level of pride and pleasure obtained; (2) good when it was active but with slight to moderate difficulty at times and with limited pleasure capacity; (3) fair when he socialized with great difficulty, readily became anxious, and had a lack of pride and limited and infrequent pleasure; and (4) poor when his behavior was seclusive or his relations were chaotic.

Amelioration of Anxiety.—Second, the patient's anxiety and its degree of amelioration were measured. Anxiety is defined here in its broadest aspect. I consider it synonymous with fear, whether this fear is generated by unconscious conflict or actual difficulties, and I attempted to quantify anxiety according to a four-point scale after analyzing this psychophysiological phenomenon into several components; namely, motor, affectual, verbal, and autonomic. The scale was as follows: (1) calm, no restlessness, overt expression of fear, when it occurred, appropriate to the severity of the actual stress; (2) slight restlessness, slight affectual expression of fear, slight pressure of speech; (3) marked

---

From the Neurological Institute of the Presbyterian Hospital of New York and the Department of Neurology, Columbia University.

Read in part before the 14th Annual Meeting of the Electro-Shock Research Association, San Francisco, May 11, 1958.

restlessness, pacing, marked overt affectual expression of fear, often severe pressure of speech; and (4) panic.

Amelioration of Initial Symptoms.—The third criterion, degree of amelioration of initial symptoms, was also marked on a four-point scale, as follows: (1) excellent, all symptoms completely gone; (2) good, symptoms markedly reduced in intensity and frequency, patient able to cope with them; (3) fair, slight improvement only with the symptoms continuing to plague patient most of the time and with marked impact; and (4) poor, symptoms unchanged.

Dreams.—Whenever possible, dreams were sought out and studied in an attempt to gain additional information. Disappearance of nightmares, decrease in the frequency of rage dreams, and increase in the frequency of pleasant dreams were points evaluated.

Final Improvement Rating.—The final improvement rating, on a four-point scale, took into account all factors described above: (1) excellent: full-time efficient employment, active and comfortable in social performance, marked pride and pleasure from vocational and social performance; (2) good: full-time employment but requiring slightly greater effort than usual, active socially but with slight to moderate difficulties at times, slight residual anxiety, symptoms markedly reduced in intensity and frequency, limited pride and pleasure from performance; (3) fair: working but with considerable difficulties and frequent absences, socializing with great difficulty, moderate to marked residual anxiety, slight improvement in symptoms but minimal pride and pleasure from performance; and (4): poor, unable to perform vocationally or socially, anxiety level severe and unchanged, symptoms unchanged, absence of pride and pleasure from performance.

Electroshock Therapy After Failure of Intensive Drug Therapy

I treated with electroshock therapy 170 severely ill patients who were first exposed to intensive treatment with various tranquilizing drugs. Prior to the onset of electroshock therapy all were very ill, unable to perform vocationally or socially in addition to being plagued by disturbing symptoms. There were 108 women, ranging in age from 22 to 74 years, and 62 men, from 25 to 71 years of age. There was a broad range of diagnosis of psychotic illnesses commonly seen in active neuropsychiatric practices and in clinics; 94 patients had schizophrenia, of whom 33 were classed as mixed; 20, catatonic; 20, depressed; 12, pseudoneurotic; and 9, paranoid. Sixty-one had involutional melancholia; 11, organic psychoses; and 4, manic-depressive psychoses.

The duration of illness in this group of patients prior to their electroshock treatments ranged from three weeks to eight years, most of them having been very sick for from one to eight months. Therapy with phenothiazine derivatives was administered for at least two weeks and with reserpine for a minimum of three weeks before institution of electroshock therapy. Some workers, especially those in large public institutions, will claim that these periods are not long enough in some instances to test the efficacy of the tranquilizers. I would answer this claim with the facts that those patients who were switched to electroshock therapy after two to three weeks of therapy with tranquilizers were becoming much worse and were in many instances a danger to themselves or to the community. Second, it was my experience with the phenothiazines [3a] that if they did not begin to produce definite results during the first few weeks of treatment, providing the dosages were in the higher range, the chances for effective results were poor. Similar results have occurred with the use of reserpine in private practice; if definite benefit is not noted in three weeks there is little likelihood of any significant changes from the drug.

The patients had received a variety of the more popular tranquilizers; 89 were receiving therapy with chlorpromazine hydrochloride; 58 with promazine hydrochloride; 57 with prochlorperazine; 40 with perphenazine; 45 with reserpine; and 68 with meprobamate. As will be noted from the figures many patients had received two or more drugs before electroshock therapy was instituted.

Those patients given chlorpromazine or promazine received the drug for a minimum of two weeks at maximum dosages of 600 mg. per day. Those given prochlorperazine received the drug for two or more weeks, the maximum daily dose being 125 mg. Patients given perphenazine remained on the drug for two or more weeks, the maximum daily dose being 64 mg. Those on reserpine were treated for a minimum of three weeks, and the maximum daily dose was 5 mg. Twenty-six patients received combined treatment with reserpine and chlorpromazine. In addition, 68 patients had received treatment with meprobamate ranging from 3,000 to 8,000 mg. per day.

In spite of drug therapy these patients remained unable to perform vocationally or socially. Before electroshock was instituted drug therapy was discontinued for 48 hours in the case of the phenothiazines and 72 hours for reserpine. Most patients had not had drug therapy for a week. The patients received from 5 to 18 electroshock treatments (EST), the average being 8. Each patient served as his own therapeutic control. Of the 170 patients 69 (41%) improved under electroshock therapy to the point of improvement rating 1; 48 (28%) to the point of rating 2; 21 (12%) showed the slight improvement of rating 3; and 32 (19%) remained unchanged (rating 4).

Of 170 patients 117 (69%) achieved improvement ratings 1 and 2; that is, they improved to the point of being able to function socially and vocationally on a high plane of efficiency and with a marked degree of pride and pleasure. Only those persons who continued to function at these levels for a minimum of three months were included in groups 1 and 2. The table shows level of improvement related to type of illness. It will be noted that 83% of those who were diagnosed as having involutional depressions had very good results and were included in groups 1 and 2, as compared with 65% of the schizophrenic patients. Analyzing the results further I found that of the 53 patients who failed to respond to electroshock therapy 39 had been ill for more than a year. The time relationship is striking when it is noted that 26 of the 33 schizophrenic patients who were therapeutic failures had been acutely psychotic for more than a year and were severely regressed.

Another group of 86 patients, who had obtained only transient improvement from electroshock treatments administered by other psychiatrists, was also reviewed. They were treated intensively with several of the phenothiazine derivatives (i. e., 66 patients given up to 1,000 mg. of chlorpromazine per day; 9, up to 1,000 mg. of promazine; 6, up to 250 mg. of prochlorperazine; and 4, up to 80 mg. of perphenazine. Nineteen (23%) of these patients responded very satisfactorily, and 37 of the remaining 66 responded to subsequent series of electroshock.

Electroshock Therapy in Combination with Tranquilizing Drugs

A total of 131 patients were treated with electroshock therapy in combination with tranquilizing drugs as follows: 123 had EST in combination with phenothiazine derivatives, of whom 96 had chlorpromazine; 12, promazine; 9, prochlorperazine; and 6, perphenazine; 4 had EST in combination with reserpine; and 4, in combination with meprobamate. All patients had been treated intensively with one or more of the above-named drugs without significant improvement, and all were severely ill. Eighty-seven were women ranging in age from 21 to 73 while 44 were men, aged from 22 to 69. There were among them 78 patients with schizophrenia, of whom 33 were classed as mixed; 16 as depressed; 15, pseudoneurotic; 8, catatonic; and 6, paranoid. There were 49 patients with involutional depressions, 2 with manic-depressive psychoses, and 2 with organic psychoses. Sixty-two of the patients had had EST previously. The duration of illness in patients in this series prior to the onset of combined treatment ranged from five weeks to 10 years, most patients having been very ill for from six weeks to 10 months.

The therapeutic technique was as follows: The patients continued to take the same total daily dose of a tranquilizing drug as they had prior to the onset of EST. The daily doses of the phenothiazines during EST ranged from 200 to 800 mg., with an average dose of 500 mg. for chlorpromazine and promazine; from 60 to 175 mg., average dose 100 mg. for prochlorperazine; and from 24 to 64 mg., average 48 mg. for perphenazine. The daily doses of reserpine ranged from 2 to 15 mg., average dose 6 mg.; and the daily doses of meprobamate ranged from 1,600 to 4,800 mg., average 2,000 mg. Premedication with intravenously given thiopental and succinylcholine was routine. A total of 1,024 combined treatments was given. The individual series ranged from 4 to 21 treatments, with the average about 8.

In general, in our experience, there was no significant advantage in using electroshock therapy in combination with the phenothiazine preparations over routine electroshock therapy by itself, except in a few limited situations that will be pointed out. In this, the impression of others[1] that combined treatment with ECT and chlorpromazine reduces the total number of treatments required for good results was not confirmed. If one reviews the literature on this point one gathers that there is no convincing statistical documentation to substantiate the impressions of the authors. I found the average number of treatments per patient with combined therapy to be the same as for a group of 150 patients, with similar diagnoses, treated with EST alone.

Improvement with Electroshock After Failure of Drug Therapy Related to Type of Psychosis in 170 Patients

Original Diagnosis	No. of Patients	Improvement Rating							
		1		2		3		4

The improvement ratings with combined therapy were statistically very close to the ones obtained with EST alone. We found that 94 (72%) of the 131 patients treated by the combined technique were able to function socially and vocationally as they had prior to the onset of their psychoses. The breakdown as for the group treated with EST alone was as follows: 41 (31%) of the 131 patients achieved an improvement rating of 1; 53 (41%) a rating of 2; 19 (15%), 3; and 18 (13%), 4. There were no specific benefits from combined treatment for patients with schizophrenia or agitated depressions. As with all other therapies the more chronic the illness the poorer the results. This study could not confirm the impressions of those who claimed that combined therapy was superior to EST alone in the treatment of the chronic psychoses.[4]

I did not find that there was any lessening of the painful anticipation and anxiety that so often precedes electroshock therapy with the combined phenothiazine-EST technique, nor could I confirm the impressions of some[5] that EST in combination with the tranquilizing drugs decreased or in any way abbreviated postelectroconvulsive organic psychoses.

There are, however, several specific instances in which combined therapy is of definite benefit. The first is in the management of some wildly agitated psychotic patients, such as may be seen among those who have catatonic schizophrenia or agitated depressions, and in the management of the now rather rare but severe manic phases of manic-depressive psychosis. If parenterally administered chlorpromazine or promazine fails to tranquilize the patients sufficiently, intense daily EST remains the preferred treatment. I did not find that therapy with phenothiazine and EST shortened the time required to relieve these states effectively, but intravenous and/or intramuscular administration of chlorpromazine or promazine given at intervals between shock treatments in some instances rendered the patient more manageable during the first few days. Combined therapy was also of help in managing those patients who became agitated during the EST series. Parenterally given phenothiazines may be effective in keeping the patient relatively calm between the electroshock treatments.

Combined therapy may be of benefit in yet another instance. It is of definite help as maintenance therapy in some psychotic patients who obtain only transient or incomplete remissions from EST or drug therapy alone. Electroshock treatments at intervals of several weeks plus oral therapy with phenothiazines have enabled us to keep a few chronically ill patients functioning vocationally and socially, though admittedly on a marginal level, whereas without such therapy they would have required long-term institutionalization.

Finally, although it is not, strictly speaking, "combined therapy," the phenothiazines are of definite help in controlling the agitation and restlessness that often accompany the organic psychoses which commonly follow a series of electroshock treatments for a period of one or two weeks.[6] If the agitation does not subside by then, further EST is indicated.

Complications of Combined Therapy

I have not found combined therapy with phenothiazine and EST to be any more difficult to manage or more dangerous than EST alone. This is in accordance with the findings of other observers.[1a] It did not prolong post-EST apnea, nor was it associated with untoward hypotensive reactions. There was no evidence of potentiation with the intravenously administered thiopental or succinylcholine.

There was only one severe complication in a patient receiving combined therapy. This was a poor-risk, severely depressed patient who was treated after other techniques failed. The patient was 63 years of age and had chronic auricular fibrillation which for the most part was controlled by quinidine therapy; he had had three transient hemiparetic episodes due to emboli and was being given anticoagulant therapy. Because high dosages of chlorpromazine, promazine, and reserpine, singly and in combination, had failed (these were the drugs available at the time), and because the patient's strong suicidal drives were a constant threat, after continued consultation with cardiologists it was decided that electroshock should be instituted. No difficulties were encountered during the first seven combined treatments. In the course of his eighth treatment he developed cardiac arrest of sufficient duration to cause cortical and subcortical dysfunctioning that fortunately cleared. This complication cannot be attributed specifically to the use of the combined therapy, as it could just as readily have occurred in this type of poor-risk patient with EST alone.

My experience with combined therapy with EST and reserpine and EST and meprobamate is not sufficient to draw conclusions from. EST-reserpine therapy was not stopped because of any untoward complications, but rather because reserpine in general was found to be too cumbersome for use in ambulant patients. Similarly, use of the meprobamates in psychotic patients has been all but discontinued, since beneficial results with this drug have been very infrequent.

Although there are a number of published reports attesting to the dangers of combined EST-chlorpromazine and EST-reserpine therapy, they do not include any well-documented large series of cases in which the physical status of the patients was studied and documented prior to therapy. On the other hand Ayd,[1a] after canvassing 179 psychiatrists, found that almost 400,000 combined treatments were given with either EST and chlorpromazine or EST and reserpine without significant difficulties being incurred.

In evaluating our statistics and results one should keep in mind that most of the patients described here were ill for a relatively short period of time as compared with patients studied in large public institutions. Very few showed any deterioration. Also, since all were seen in private practice or on outpatient bases, our criteria for improvement, as mentioned above, depended primarily on the degree to which the patient was able to resume functioning vocationally and socially and how much pride and pleasure was associated with this performance. Therefore, in comparing our findings with other reports on the relative effects of the tranquilizers as compared with EST or of the relative advantages of combined therapy with tranquilizers and electroshock, it would be necessary to compare the following points: (1) whether the patients reviewed were inmates of state hospitals or patients seen in private practice or on an outpatient basis; (2) the duration of illness and degree of regression or deterioration; and (3) the criteria established for estimating the degree of improvement.

Summary

Failures with intensive phenothiazine, reserpine, or meprobamate therapy do not, by any means, rule out the possibility of obtaining good results in psychotic patients for whom electroshock therapy (EST) is indicated. Of 170 psychotic patients who failed to benefit from the tranquilizing drugs 69% had satisfactory results with EST. Combined therapy with phenothiazines and electroshock, in general, neither reduced the total number of electroshock treatments required for good results, decreased the degree of pre-EST apprehension, nor shortened the postconvulsive organic psychoses.

Parenterally given phenothiazines are helpful in managing some of the more agitated or manic patients in the intervals between electroshock treatments during the first few days of therapy. They also may be of aid in calming the agitation that may occur during an EST series and in the management of the agitation and restlessness associated with the post-EST organic psychoses.

Combined therapy, in my experience, carries no greater risk than EST alone. I did not find it necessary, in general, to discontinue the phenothiazine drugs before starting EST. I do not recommend the routine use of electroshock therapy in combination with the phenothiazines, because it was not found to be more advantageous than EST alone, except in a few specifically designated instances.

CHOICE OF ANESTHETIC AGENT.—The idea of specific choice of anesthesia or anesthetic agent has been based upon two rather broad concepts. The first of these is that certain disease states require or are harmed less by a certain type of anesthetic agent. The second is that there exist certain rather definite contraindications and indications for each particular anesthetic agent. . . . These concepts are not valid. . . . Evidence for my stand on this matter is the fact that many clinics and practicing groups have widely varying choices of anesthetic techniques and management with no apparent difference in results. Such would hardly be the case if there were one definitely superior method or one superior agent to be used. . . .

The common concept that heart disease contraindicates the use of cyclopropane is based upon the belief that arrhythmias are due to the toxic effect of the agent. . . . These undesirable events are due either to overdose of the agent, which can hardly be blamed on the agent itself, or to hypoventilation or asphyxia occurring concurrently with the administration of the agent. One might look at the cyclopropane question in another way and ask: What better agent for a sick heart could one desire than one which is rapid, not unpleasant, very flexible, offers a minimal excitement phase, and probably offers less depression of myocardial function for a given level of central nervous system depression than other inhalation agents? —W. K. Hamilton, M.D., Fallacies in Choice of Anesthetic Agent, *Transactions of the American Academy of Ophthalmology and Otolaryngology*, March-April, 1959.

CHLOROTHIAZIDE—A SURVEY OF ITS EFFECTS IN HYPERTENSIVE PATIENTS

Carl C. Bartels, M.D., James A. Evans, M.D.
and
Robert G. Townley, M.D., Boston

A definite hypotensive effect from chlorothiazide was observed in 80% of 65 patients studied. This was more pronounced in those with severe hypertension and in those receiving ganglionic blocking agents. Of the 23 patients who had formerly required ganglionic blocking agents, 12 were able to discontinue that therapy. It would seem that periodic determinations of the serum potassium level are necessary in any patient who is receiving chlorothiazide on a long-term basis. Twenty-eight patients (43%) in this group showed a drop in potassium level to 3.5 mEq. per liter or below. This occurred in 12 despite the concurrent administration of 2 to 3 Gm. of potassium chloride daily. It is now well recognized that renal lesions may accompany potassium deficiency in man. Symptoms of this may be minimal and their onset insidious. There is also danger of hypokalemia potentiating digitalis poisoning.

Chlorothiazide (Diuril) is a potent drug in the treatment of hypertension and is now one of the most widely used drugs for that purpose. The drug produces a hypotensive effect only in hypertensive persons,[1] but its mode of action is still unknown. It also has diuretic and saluretic effects. Moyer and associates [2] have suggested that through its diuretic action total blood volume is decreased—thereby potentiating the effect of ganglion blockade. These authors noted no significant reduction in blood pressure when this drug was administered to a group of patients who had never received blocking agents. Freis and co-workers,[3] however, noted that, in addition to its potentiating action of ganglionic blockade, chlorothiazide is a hypotensive agent in its own right. They measured the effect of chlorothiazide in 10 previously untreated, hospitalized patients without edema in whom basal blood pressure readings were obtained for six days before the administration of 1.5 Gm. of chlorothiazide daily for six days. The results showed some decline in blood pressure in every case, with an average drop of 17% in the mean blood pressure. Wilkins and associates [4] confirmed the findings of Freis and co-workers that chlorothiazide is a potent hypotensive agent both alone and in combination with other drugs.

The use of chlorothiazide at the Lahey Clinic was begun in November, 1957. Since then we have attempted (1) to evaluate its effects as a hypotensive agent, (2) to compare its effectiveness with and without the simultaneous use of ganglion blocking agents or previous splanchnicectomy, (3) to determine its effect on potassium excretion as measured by the serum potassium levels and electrocardiographic changes, and (4) to determine the indications for and contraindications to its use in the treatment of hypertensive patients.

Wilkins and associates,[4] in their original paper on chlorothiazide as a hypotensive drug, pointed out the potential danger of the loss of electrolytes of sodium and potassium. Hyponatremia may cause weakness, lassitude, and muscle cramps, but the loss of potassium presents a real danger in patients taking digitalis. The potentiation of digitalis effect in patients with hypokalemia may cause cardiac standstill. Wilkins [4A] postulated this possibility as a cause of death in six digitalized patients early in his experience with chlorothiazide.

A combination of diuresis from mercurial diuretics and hypokalemia from chlorothiazide and digitalis could be fatal. A long-sustained, unrecognized hypokalemia resulting from chlorothiazide could cause a specific tubular type of nephritis. It was for the purpose of preventing such potential complications that we undertook to study our patients with regard to the effect of chlorothiazide on the potassium level of the blood serum.

Methods

A knowledge of the variables that will be encountered is important in studying any hypotensive agent. One example is the discrepancies of blood pressure readings in the home, office, or hospital as taken by the patient, physician, or nurse respectively. The efficacy of any antihypertensive therapy is dependent on an adequate evaluation of the severity of the disease before treatment is initiated.

A series of 65 patients with hypertension without edema was used as the basis for our study. Twenty-one of these patients had grade 3 or 4 hypertension as determined by the Keith-Wagener-Barker method for the classification of ocular fundal changes. Additional data regarding cerebral, cardiac, and renal function were included in the evaluation of the hypertensive status. In 23 cases, ganglion blocking agents had been given prior to and during the initiation of chlorothiazide therapy; splanchnicectomy had been performed previously on seven

From the Department of Internal Medicine, Lahey Clinic.

patients. Thirty-three patients were hospitalized for four to seven days before chlorothiazide therapy was begun so that basal blood pressure readings could be determined. All patients who were started on chlorothiazide therapy in the clinic had had follow-up studies for at least three months to as long as several years, and the basal blood pressures were determined by averaging the previous readings. These were compared with the average blood pressure reading over the ensuing period of treatment, which ranged from two to seven months. While therapy with the previously given hypotensive drugs was continued, 0.25 Gm. of chlorothiazide was given twice daily in most cases—the maximum daily dose being 1.0 Gm. and the minimum daily dose 0.25 Gm.

Data from Twenty-eight Patients in Whom Serum Potassium Levels Decreased to 3.5 mEq. per Liter or Below

63	4		1.8	14	0.50	2	none*	14	Symptoms of weakness: prolonged Q-T interval (see text)
65	1 (splanchnicectomy)	4.2*	2.9	70	0.25	2	0.25		70 days later, below 3.5 mEq./liter; chlorothiazide therapy stopped for 1 wk., then one-half of dose given; potassium chloride increased to 3 Gm. daily; serum potassium level still only 3.3 mEq./liter 6 wk. later

* Potassium chloride therapy started after low result of serum potassium determination (in our laboratory, standard deviation for serum potassium level is 1 mEq. per liter, with a normal range of 3.3 to 5.8 mEq. per liter).

Serum potassium determinations were obtained twice a week for the first two weeks and then twice a month or at monthly intervals on return visits to the clinic. Serum sodium values were determined in 47 patients, and all patients were given a 4-Gm. sodium diet during the study.

Results

A decrease in the mean blood pressure of over 10% was noted in 52 patients (80%). Only 2 of the 21 patients with grades 3 and 4 hypertension showed less than a 10% drop in the mean blood pressure. Of the 23 patients receiving ganglionic blocking agents, three failed to show a significant drop in blood pressure.

One of these three (case 63) was a 36-year-old man with a one-year history of malignant hypertension. He had received 0.5 Gm. of chlorothiazide twice daily for three weeks in another hospital before entering the New England Deaconess Hospital, Boston; pentolinium (Ansolysen), 20 mg. four times daily, had also been given. Two episodes of transient aphasia had occurred in the previous two weeks. On admission, the blood pressure was still 250/150 mm. Hg. Chlorothiazide therapy was discontinued because of hypokalemia with a serum potassium level of 1.8 mEq. per liter. At this point he suffered a cerebral hemorrhage with hemiplegia. During the next three weeks of hospitalization, the blood pressure was controlled with hexamethonium. He was discharged on a regimen of mecamylamine (Inversine) hydrochloride and reserpine (Serpasil).

Another patient (case 51), a 32-year-old man with a 13-year history of hypertension, was admitted to the hospital with grade 3 to 4 hypertension. He had been receiving chlorothiazide (0.25 Gm. twice daily) for 15 weeks, along with mecamylamine, 2.5 mg. twice daily, and reserpine, 0.25 mg. twice daily. Because he was emotionally unstable, tense, and nervous as a result of hypertensive encephalopathy, he could not be treated on an outpatient basis; moreover, the blood pressure showed no response to chlorothiazide and the ganglionic blocking agents even in the hospital. He was therefore subjected to bilateral splanchnicectomy. After this, not only was a dramatic response seen in the blood pressure but also the retinal hemorrhages cleared and emotional lability improved.

The third patient (case 53) who failed to show a response to chlorothiazide was a 54-year-old woman with a 14-year history of hypertension. She was receiving mecamylamine (2.5 mg. twice daily) and Rauwolfia for grade 2 hypertension. No response in blood pressure was noted after chlorothiazide was added to this regimen. It may be of significance to add that in all three of the above patients who failed to show a response to chlorothiazide a fall in serum potassium levels to 2.0 and 3.0 mEq. per liter occurred despite the coadministration of 2 to 3 Gm. of potassium chloride daily. Thus, these three patients demonstrated a diminished ability to conserve potassium while chlorothiazide therapy was given.

Of the seven patients who had previously undergone splanchnicectomy, a pronounced drop in blood pressure was noted in all cases—the average drop being 52/39 mm. Hg or a 27% fall in the mean blood pressure. Three of these showed a marked hypotension, and the dosage of chlorothiazide was limited to 0.125 Gm. given twice daily. Two patients who had had splanchnicectomy were given ganglionic blocking agents; both were able to discontinue therapy with these agents when chlorothiazide was administered.

Therapy with ganglionic blocking agents was discontinued in 12 patients, and in an additional 6 the dosage could be reduced by two-thirds or one-half. Thus, the usual dosage had to be continued in only 5 of the 23 patients. Although a drop in blood pressure was noted during chlorothiazide therapy in 77% of the patients with grades 1 and 2 hypertension, it was usually less than that demonstrated in the patients with grades 3 and 4 hypertension. Of the 13 patients who showed less than a 10% fall in the mean blood pressure, the hypertension was classified as grades 1 and 2 in 10. Blood pressures returned to normal levels in 28 of the 65 patients; in 6 additional patients the diastolic pressure re-

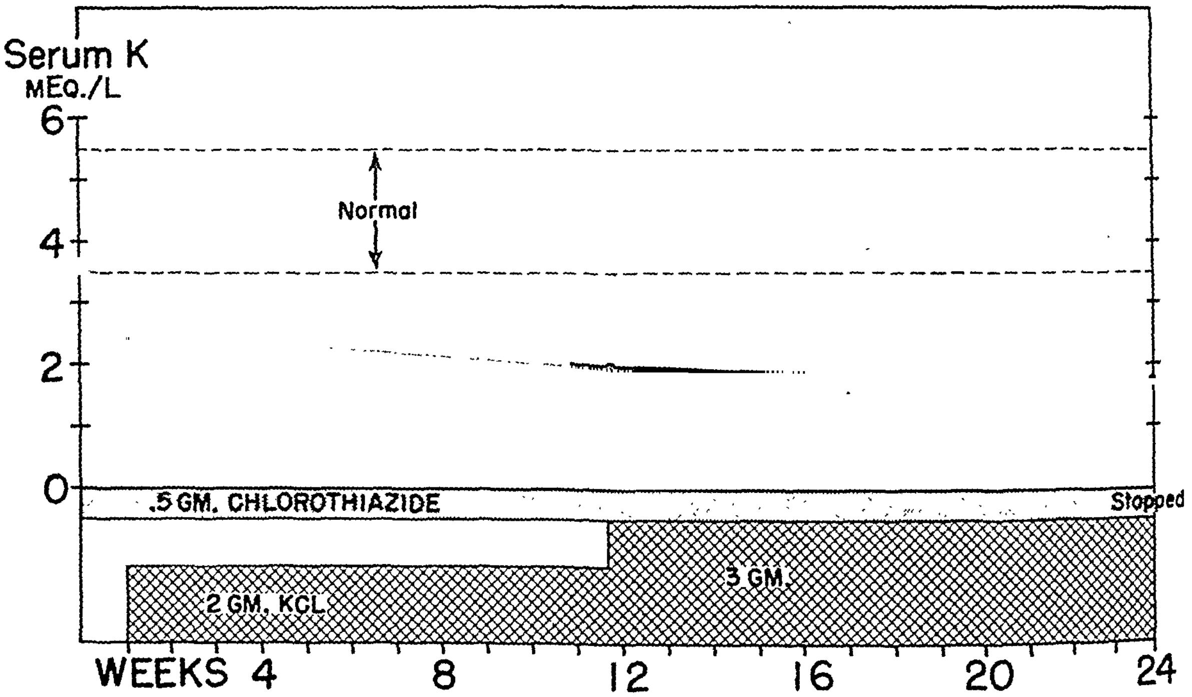

Fig. 1 (case 48).—Inability to conserve potassium. Serum potassium level continued to drop to level of 1.8 mEq. per liter despite administration of 3 Gm. of potassium chloride daily.

turned to a normal level. Thus, approximately one-half of the patients had normal blood pressure readings after chlorothiazide was added to the program of therapy.

The striking finding in the group of 65 patients studied was the fact that 28 patients (43%) showed a drop in serum potassium levels to 3.5 mEq. per liter or below, as demonstrated in the table. Of these 28 patients, the average fall in serum potassium level was 1.5 mEq. per liter, despite the fact that 12 patients had received 2 or 3 Gm. of potassium chloride daily from the time chlorothiazide therapy was started. One patient (case 55) received only 0.25 Gm. of chlorothiazide every other day, and the serum potassium level fell to 3.3 mEq. per liter. In another patient (fig. 1, case 48), who received 0.25 Gm. twice daily, the serum potassium level fell to 1.8 mEq. per liter and the electrocardiogram showed definite hypokalemic changes despite the concurrent administration of 3 Gm. of potassium chloride daily. However, the hypertension changed from grade 3 to grade 1 six months after chlorothiazide therapy was begun, and the patient was able to stop taking mecamylamine four months after administration of chlorothiazide was initiated. One of the patients (case 63) mentioned above as having no fall in blood pressure while receiving 0.5 Gm. of chlorothiazide twice daily for three weeks, along with pentolinium and hydralazine (Apresoline) for malignant hypertension, exhibited a decrease in serum potassium level to 1.8 mEq. per liter with symptoms of nausea and weakness. The electrocardiogram demonstrated pronounced hypokalemia, with the Q-T interval prolonged to 67% of the R-R interval. He had not received potassium chloride, and the blood pressure had remained at 250/150 mm. Hg. As evidence of pronounced potassium depletion, 40 mEq. per liter of potassium chloride was administered intravenously each day for one week before the serum potassium level reached a level of 3.7 mEq. per liter. This same patient also exhibited signs of hypochloremic alkalosis, with an initial carbon dioxide–combining power of 34 mEq. per liter and chloride level of 92 mEq. per liter. The aldosterone assay gave normal results.

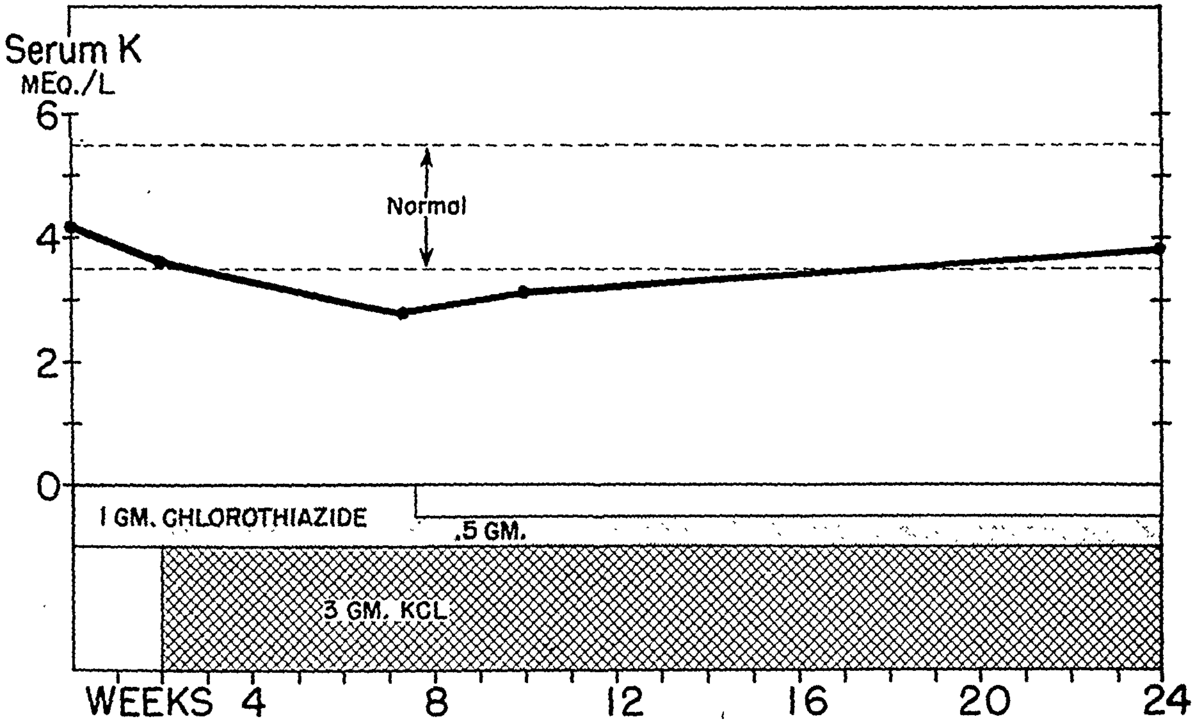

Fig. 2 (case 45).—Graph illustrating necessity of lowering dosage of chlorothiazide when potassium chloride has been added and serum potassium level continues to fall.

Three patients could not tolerate potassium chloride because of gastric irritation. It was necessary to stop chlorothiazide therapy because of low potassium levels in only two instances (case 48 [fig. 1] and case 63).

The fall in serum potassium level will usually be apparent after seven days. However, in one patient (case 54) the serum potassium level dropped from 4.5 mEq. to 3.3 mEq. per liter on the fourth day after chlorothiazide therapy was instituted.

Frequently, the lowest serum potassium level was not reached until four to six weeks after chlorothiazide therapy was started, as shown in figures 2, 3, and 4. The administration of 2 to 3 Gm. of potassium chloride daily usually brought the serum potassium level back to normal. There were many exceptions to this, however, and in a few instances the serum potassium value continued to decline but would no doubt have fallen even more had potassium chloride therapy been withheld.

Comment

Our experience at the Lahey Clinic has shown that chlorothiazide is an effective agent in the treatment of hypertension. Because it augments blood pressure response to other hypotensive agents, smaller and less frequent doses of the latter are needed. Thus, one of its greatest advantages is in the treatment of patients with grades 3 and 4 hypertension. In such cases the dose of ganglionic blocking agents may be either cut in half or entirely eliminated, thereby reducing the side-effects to a tolerable level. In addition to decreasing the side-effects, it decreases the pronounced fluctuation in blood pressure that accompanies the administration of various ganglionic blocking agents. We concluded that chlorothiazide not only potentiates the effect of other hypotensive agents but also appears to have a decided antihypertensive influence in its own right.

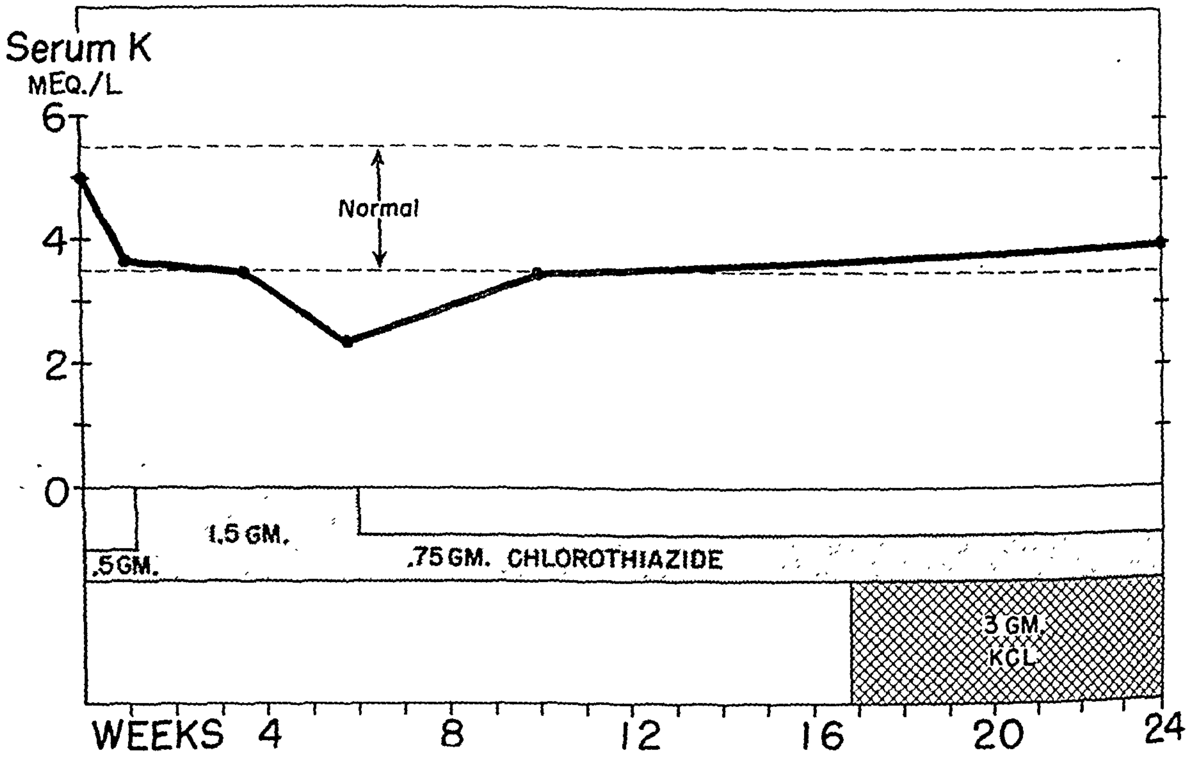

Fig. 3 (case 49).—Return of serum potassium level to normal limits with decreased dosage of chlorothiazide and addition of 3 Gm. of potassium chloride.

Chlorothiazide administered orally in doses of 500 mg. each day can produce a significant change in the serum potassium level. In our series a drop to 3.5 mEq. per liter or below was noted in 43% of the patients. This is substantially greater than the decrease reported earlier by Wilkins and associates.[4] In their series, only 3 of 17 patients showed a drop in serum potassium level below 3.7 mEq. per liter. Moreover, in our series the average daily dose was 500 mg., whereas they used 750 mg.

In only 6 of the 28 patients in whom the serum potassium level dropped to below 3.5 mEq. per liter did it return to normal without the help of either potassium chloride supplement or reduction of the dosage of chlorothiazide. The drop occurred in many instances despite the concurrent administration of 2 to 3 Gm. of potassium chloride daily.

It may be seen in the table, however, that there were many exceptions; in 10 cases the potassium level remained below 3.5 mEq. per liter for a much longer time. The long-term use of drugs which may cause potassium depletion must be carefully considered in these patients who are potential potassium wasters.

Considerable evidence has indicated that potassium deficiency may cause significant alterations in renal structure and function.[5] Dietary deficiencies of potassium in rats and mice produce enlargement of the kidneys and striking changes in the tubular structure.[6] The increase in size begins within a few days, and the kidneys often become twice normal size in two weeks. The most striking changes occur in the collecting tubules where swelling, hyperplasia, and granulation [7] are noted. Restoration of potassium to the diet has resulted in virtually complete healing of the characteristic lesion.[8] However, other observers have noted interstitial scarring, hyalinized glomeruli, and dilated tubules several weeks or months after correction of a deficiency which lasted for six to eight weeks.[6]

It is now well recognized that renal lesions may accompany potassium deficiency in man.[5] Such changes have been described in various diseases associated with potassium deficiency; depletion produced by diarrhea in ulcerative colitis or bacillary dysentery and chronic small intestinal fistulas; adrenal disease such as adrenal cortical hyperfunction (Cushing's syndrome), primary aldosteronism, and the condition after cortisone treatment; and, finally, renal diseases with potassium wasting, such as renal tubular acidosis and macrocytic anemia (Fanconi's syndrome), subacute glomerulonephritis, and chronic pyelonephritis.

The minimum duration and severity of the potassium depletion required to produce these changes in man are not known, but the condition has usually been present for many months before such changes occur. In many of our patients, the serum potassium level was below 3.5 mEq. per liter on return visits over a period of several months. Because this occurred in some instances despite added potassium, it would seem advisable to reevaluate renal function in these patients who have proved to be potassium wasters. Thus far we found no alteration in renal function.

Postmortem observation of changes in renal structure in patients who had received chlorothiazide with prolonged potassium depletion will provide the final answer. We know of no such reports, nor have we seen a patient who has had digitalis poisoning potentiated by hypokalemia resulting from chlorothiazide therapy. The danger of such an occurrence must be borne in mind, however.

Summary

The effect of chlorothiazide was studied in a series of 65 hypertensive patients. A definite hypotensive effect was observed in 80% of the patients. This effect was more pronounced in patients with severe hypertension and in those receiving ganglionic blocking agents; it was most pronounced in patients who had previously undergone splanchnicectomy.

Of the 23 patients who had formerly required ganglionic blocking agents, 12 were able to discontinue that therapy and an additional 6 were able to reduce the dosage to one-half or less when chlorothiazide was administered.

Twenty-eight patients (43%) showed a drop in serum potassium level to 3.5 mEq. per liter or below. This occurred in 12 patients despite the concurrent administration of 2 to 3 Gm. of potassium chloride daily. It is now well recognized that renal lesions may accompany potassium deficiency in man. We know no way of predicting which patients will show potassium waste, since in our series depletion has occurred with or without impaired renal function.

The symptoms of potassium deficiency may be minimal and their onset insidious. It would seem that periodic determinations of the serum potassium level are necessary in any patient who is receiving chlorothiazide treatment for hypertension on a long-term basis. Such patients should be instructed

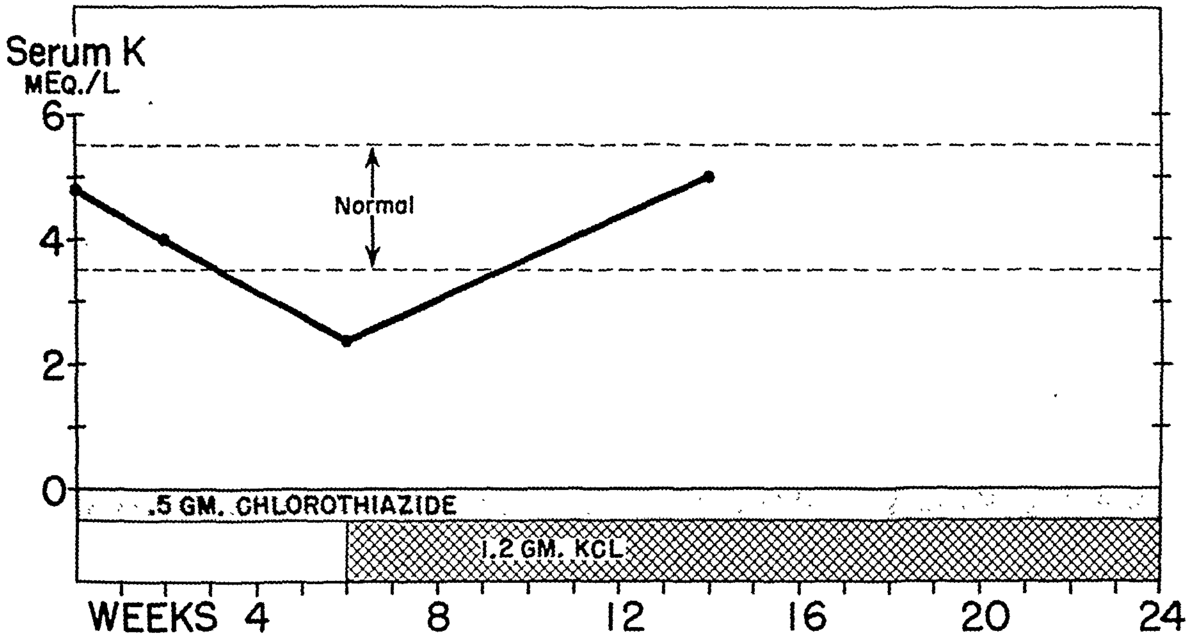

Fig. 4 (case 52).—Usual response of serum potassium level when potassium chloride has been added.

to interrupt the use of this drug when conditions associated with diarrhea or vomiting occur. When these conditions are present, the additional potassium losses that occur could result in severe potassium depletion.

CLINICAL NOTES

CORONARY EMBOLUS

Stuart A. Mason, M.D., Ridgewood, N. J.

The occurrence of coronary embolus in a patient with rheumatic heart disease is an unusual complication. No means of differentiating it from acute coronary thrombosis exists.[1] One should be suspicious of acute coronary embolus if the clinical picture of acute coronary thrombosis occurs in a young patient in whom advanced coronary disease is unlikely. This suspicion should be increased, especially, if the patient has not had angina pectoris and if auricular fibrillation and mitral stenosis are present.

The most frequent cause of coronary artery embolus is subacute bacterial endocarditis. Occlusion is more common in the left artery than in the right. Two-thirds of all patients with coronary embolus due to bacterial endocarditis die suddenly; the remaining third have a longer course which simulates acute myocardial infarction. When embolism is due to disease other than bacterial endocarditis, the outcome is always fatal, according to published reports.[2]

To establish that death is due to coronary embolism, postmortem study should reveal an occluding mass in a major branch of the coronary system, as well as the site of origin of the embolus and normal arterial intima at the area of occlusion.[2] Sometimes a coronary embolus may arise from a calcified valve in a patient with healed bacterial endocarditis.[3]

A case of chronic rheumatic heart disease, with multiple emboli to the lower extremities, kidneys, and lungs and fatal embolism to the heart, is presented here.

Report of a Case

A 42-year-old woman with chronic rheumatic heart disease of many years' duration was seen because of pain and numbness in the right leg, with sudden onset one-half hour earlier. No pulsations were present in the right lower extremity, and oscillometric readings were absent. The onset of rheumatic fever occurred at the age of 10 years, with recurrence three times between the ages of 10 and 12. At the age of 21 years, the patient had scarlet fever, complicated by pneumonia, for which she was bedridden eight weeks. On recovery, she was placed on therapy with digitalis, which she had taken continuously since that time. The patient was married and had two children. Since the age of 28, she had noted a progressive loss of strength, associated with intermittent swelling of the legs and ankles.

Examination on admission to Hackensack (N. J.) Hospital showed a middle-aged, slender woman appearing chronically ill and weighing 110 lb. (49.9 kg.). Her fibrillation rate was about 90 per minute, as confirmed by electrocardiogram, which also showed digitalis effect. The heart was enlarged to the left anterior axillary line in the sixth intercostal space. The first heart sound was accented and snapping in quality. An opening snap

---

From the departments of medicine, Hackensack Hospital, Hackensack, N. J., and Bergen Pines Hospital, Paramus, N. J.

was heard. The second pulmonary sound was accentuated and split. Along the left parasternal border, a blowing diastolic murmur was heard. A grade-3 systolic murmur was present at the apex and transmitted throughout the precordium. A grade-2 presystolic murmur was also present at the apex, accompanied by a thrill.

The surgical consultant concurred in the diagnosis of embolus to the right femoral artery, and embolectomy was performed within five hours. Postoperatively the patient did well, but a postoperative electrocardiogram showed evidence of anteroseptal myocardial infarction. She was placed on anticoagulant therapy (heparin and bishydroxycoumarin) and had an uneventful convalescence. She was discharged in good condition after six weeks, with all pulsations in the right lower extremity of good quality.

About eight hours after leaving the hospital she was seen again because of numbness and tingling in her left lower extremity. These complaints had developed shortly before her discharge from the hospital, but since they were mild she did not say anything about them for fear she would not be released. No pulsations were palpable in the left lower extremity, and no oscillometric readings could be obtained. She was readmitted, but three more hours elapsed before operation, when an embolus to the profunda branch of the left femoral artery was found. An embolectomy was performed, but the dorsalis pedis pulsation still was not palpable. Because the patient's condition was deteriorating, the operation was terminated. Postoperatively, the color of the left lower extremity was good but absence of pulsations persisted and the patient complained of pain, numbness, and coolness of the leg. The pain at times was excruciating and was controlled only with narcotics. Nerve blocks were performed but did not control the pain.

After several weeks, a plastic bypass graft was inserted around the obstruction and a sympathectomy was performed simultaneously. For one day after the operation, the leg felt warmer and there was less pain. However, the pain recurred and again could be controlled only with narcotics.

She was transferred to St. Vincent's Hospital, New York City, on May 11, 1958. Physical findings were as previously reported except for a loss of weight from 110 lb. to 78 lb. (35.4 kg.). The left lower extremity was swollen and atrophic and felt cool; no pulsations were present. The right lower extremity felt warm, and strong pulses were felt in the femoral, popliteal, and dorsalis pedis arteries.

An aortogram showed obstruction of the left external iliac, common femoral, and proximal half of the superficial femoral arteries. An electrocardiogram showed fibrillation (auricular) at a rate of 100 per minute. The urine was negative for sugar and albumin but contained many white blood cells and bacteria per high-power field. The blood cell count was within normal limits. X-ray of the chest showed cardiac enlargement.

She was seen by the cardiopulmonary staff and the combined medical-surgical cardiac team, who advised against operation because of her poor general condition. Shortly afterward, she developed pneumonia of the lower lobe of the left lung, which responded to penicillin treatment. On recovery, she was seen by the medical consultant, who felt that mitral commissurotomy might help. She was discharged for convalescence at home and was to return in one month for cardiac surgery.

Two days after returning home, she was awakened by severe pain in the right flank. She was readmitted to St. Vincent's Hospital. The pain persisted for several days, but results of urinalysis were negative for red blood cells. The temperature reached a peak of 102 F (38.9 C). Five days after admission, she developed severe pain in the left flank and results of urinalysis were again negative for red blood cells. Her complaints gradually subsided, and she was discharged for convalescence at home.

The patient entered St. Vincent's Hospital for the third time on Aug. 20. Five days after her admission, a temperature of 101 F (38.3 C) was noted, associated with a loose, productive cough. Rhonchi were heard in both lung bases. After administration of penicillin, the temperature returned to normal but then rose again. Blood culture showed no growth. Pain appeared in the lower right part of the chest anteriorly, and a friction rub and rales were heard.

On Sept. 10, slight induration along the lesser saphenous vein on the left was observed, and two days later severe pain in the anterior right part of the chest occurred again. On Sept. 13, ligation of the left common femoral vein was performed with the patient under local anesthesia. The patient tolerated the procedure well, and the postoperative course was uneventful until Sept. 20, when severe pain in the anterior part of the chest, radiating to both shoulders and arms, developed. The blood pressure was 90/72 mm. Hg, pulse rate 128 per minute, thready and irregular, and respiration rate 32 per minute. The lips and nails were cyanotic. The patient had dyspnea and orthopnea and was apprehensive. The heart sounds were of good quality. Coarse rales were heard throughout the chest. An electrocardiogram showed anterior wall infarction. The patient was placed in an oxygen tent. She died about 16 hours after onset of the acute chest pain.

At autopsy, the lungs were congested and edematous, with infarction of the lower lobes of the right and left lungs. The liver and spleen were moderately congested. Both kidneys showed congestion and infarction. There was congestion also of the stomach and small and large intestines. Petechial hemorrhages were present in the stomach. The aorta showed minimal focal atherosclerosis.

The heart, weighing 450 Gm., was moderately enlarged and dilated. The left auricle contained a mural thrombus which extended to and completely filled the auricular appendage. The mitral valve showed extreme stenosis, and the mitral opening was fish-mouthed in appearance and would not admit a finger. The mitral cusps were thickened and fused. The left ventricular wall measured 1 cm. in thickness. The coronary ostia were patent, and the arteries were thin and pliable, with a pale, smooth intimal surface. One centimeter from the left coronary ostium, in the left anterior descending branch, the lumen was completely occluded by pinkish-gray, granular, friable material similar to that noted on the endocardial surface of the left auricle.

Conclusions

A case of coronary embolus occurred secondary to chronic rheumatic heart disease in a 42-year-old woman. Suspicion of coronary embolism should be aroused when the symptoms of acute coronary thrombosis occur in a young patient, especially when there is no history of angina pectoris and when auricular fibrillation and mitral stenosis are also present.

CORONARY EMBOLISM WITH MYOCARDIAL INFARCTION—COMPLICATION OF VERRUCOUS ENDOCARDITIS

Norman F. Boas, M.D.
and
Roy N. Barnett, M.D., Norwalk, Conn.

Coronary embolism, as a cause for myocardial infarction, has probably been diagnosed clinically only three or four times.[1] Small coronary emboli are usually of little clinical significance and are not infrequently seen at autopsy in cases of bacterial endocarditis [2] and in some forms of verrucous endocarditis (verrucal endocardiosis).[3] Emboli large enough to produce gross myocardial damage have been reported convincingly in only about 50 cases.[1] The literature on this subject has been reviewed several times in recent years.[4] The emboli reported have almost always been blood clots which have arisen either from lesions within the coronary arteries, aorta, or endocardium or from the lower extremities by way of a patent foramen ovale. There are only two reports of nonthrombotic emboli. These included a calcified nodule arising from the aortic valve [4b] and a caseous plug arising from the lungs in a case of pulmonary tuberculosis.[5] To our knowledge, there are only two cases in the literature with electrocardiographic evidence of myocardial infarction.[6]

The case reported here is of interest since a new type of embolic material was identified, namely, a verruca dislodged from the site of verrucous endocarditis on a heart valve. Electrocardiographic data are also presented. The infarction was diagnosed clinically.

Report of a Case

Clinical History.—The patient was a 44-year-old woman who was well until October, 1955, at which time she developed thrombophlebitis of the left leg. This was followed in six weeks by an attack of acute, severe pain in the lower part of the abdomen. An exploratory laparotomy performed at another hospital revealed a large papillary adenocarcinoma of the left ovary, for which the patient had a bilateral salpingo-oophorectomy. Despite a postoperative reactivation of the thrombophlebitis and one episode of pulmonary embolization, she gradually improved. After discharge, she was given a series of 24 x-ray treatments to the abdomen over a period of three months. Thereafter she did well until August, 1956, when she again developed thrombophlebitis of the left leg, followed by progressive enlargement of the abdomen with loss of appetite, constipation, and generalized abdominal pain. She was admitted to the Lenox (N. Y.) Hill Hospital on Sept. 12, 1956, and two days later a laparotomy was performed by Dr. John Vieta. The findings included several liters of bloody ascitic fluid, generalized carcinomatosis, and obstruction to the transverse

---

From the departments of medicine (Dr. Boas) and pathology (Dr. Barnett), Norwalk Hospital.

colon from tumor nodules. The obstructed section of the transverse colon was resected and closed with an end-to-end anastomosis. The pathologist's report indicated that the tumor was a papillary adenocarcinoma. Prior to discharge, she was treated with one intraperitoneal dose of radioactive colloidal gold and three intravenous doses of 2 mg. of triethylene melamine. The patient was discharged on Oct. 12, 1956. During the next two weeks, she required several transfusions at home.

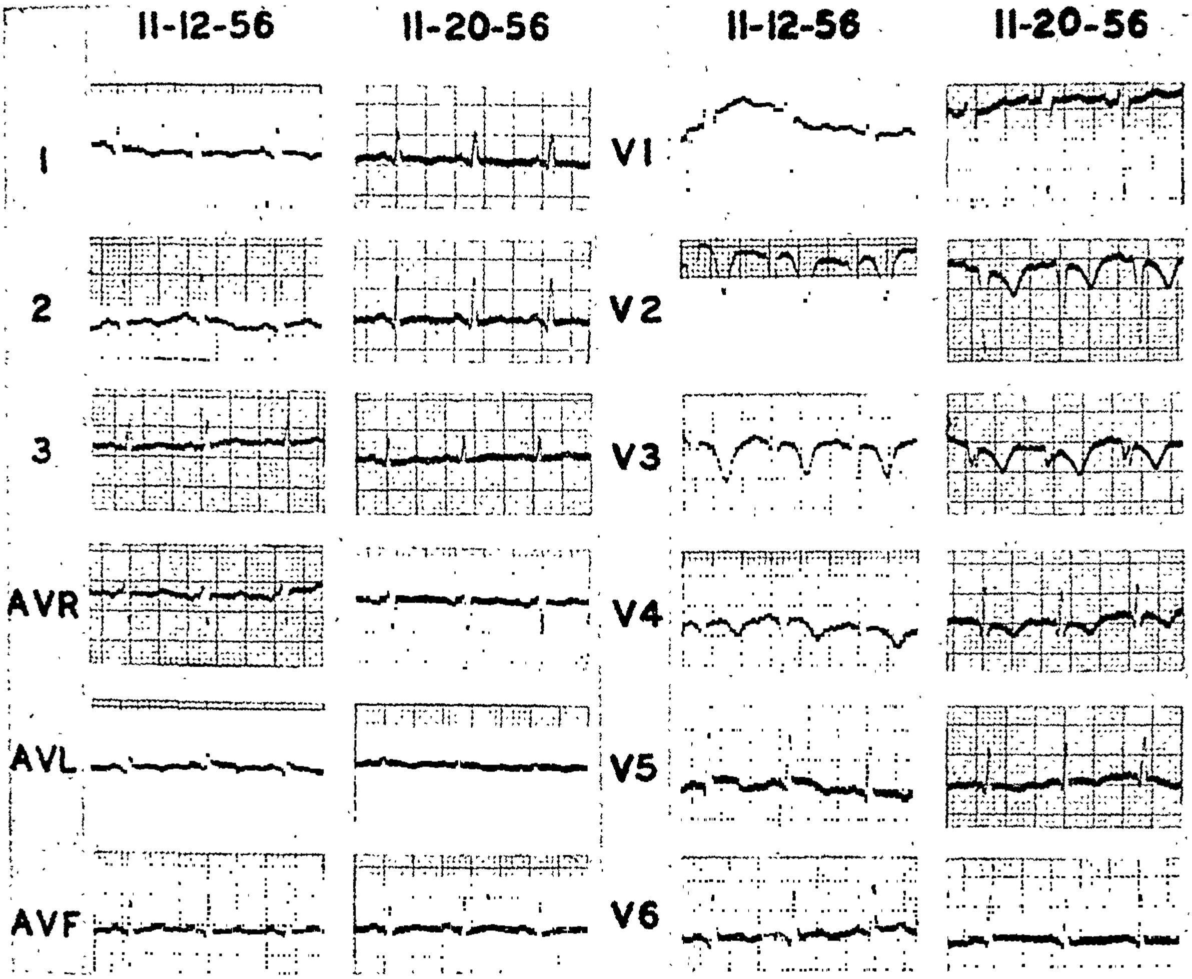

Fig. 1.—Electrocardiograms taken 14 days (11-12-56) and 20 days (11-20-56) after clinical episode of chest pain.

On Oct. 29, she had a severe bout of nausea and vomiting after which she had a crushing pain in the anterior part of the chest, radiating to both arms and to the mid-back. The patient was in a cold sweat during the attack, which lasted for several hours. She required morphine and meperidine (Demerol) throughout the night. During the subsequent 11 days prior to admission to the Norwalk (Conn.) Hospital, she experienced extreme weakness and had a persistent fever and tachycardia and became forgetful, drowsy, and apathetic.

On admission to the Norwalk Hospital, the patient was in no acute distress but was confused mentally and disoriented as to her surroundings. Complete physical examination was negative, except for evidence of marked pallor, a pulse rate of 110 per minute, and the presence of two long abdominal incisional scars. The impression on admission was that the patient either had metastatic brain damage or cerebral emboli, possibly arising from a damaged myocardium.

On admission, the hemoglobin level was 10.4 Gm.%, red blood cell count 3,120,000 per cubic millimeter, and white blood cell count 2,750 per cubic millimeter with 68% adult polymorphonuclear cells, 14% stab cells, 16% lymphocytes, 1% monocytes, and 1% basophils. Urinalysis revealed a specific gravity of 1.026, pH 7, 1+ albumin, a few white blood cells, and no sugar. The blood urea nitrogen level was 11 mg.%, chloride level 97 mEq. per liter, and Venereal Disease Research Laboratory test result negative. An electrocardiogram taken on Nov. 12 showed a pattern interpreted as a recent anterior wall myocardial infarction. Repeated on Nov. 20, the tracing was generally the same, except for a diminution in the depth of the T waves (fig. 1).

Two days after admission, a pericardial friction rub was heard over the left precordial area. Despite tube feedings, intravenous administration of fluids, penicillin, and digitoxin, and other forms of supportive treatment, the patient progressed into a state of stupor, congestive heart failure, and shock and finally died 24 days after admission.

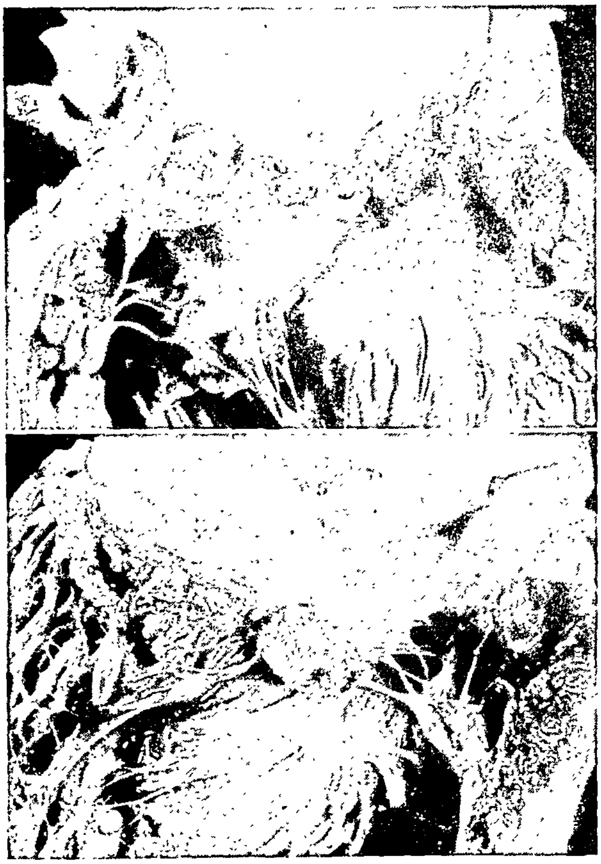

Fig. 2.—*Top,* aortic valve demonstrating many verrucous excrescences on three valve cusps. *Bottom,* mitral valve demonstrating large verrucous masses on both cusps.

Autopsy Findings.—Autopsy was performed by George W. Changus, M.D. The body was well developed but slightly undernourished. There were well-healed abdominal scars and brown pigmentation of much of the abdominal skin. Pitting edema (1+ to 2+) was present in both legs. In the peritoneal cavity there were many dense fibrous adhesions, as well as many tumor nodules confined to the underside of the diaphragm. There was one 5-cm. tumor mass in the left side of the pelvis. The heart weighed 240 Gm. On both mitral and aortic valve cusps there were slightly firm, granular, pale pink masses of friable material measuring from 5 to 20 mm. in greatest diameter (fig. 2). These masses were somewhat adherent to the valve cusps but were not associated with destruction or fibrosis of the leaflets. There were no adhesions of the commissures, and the chordae tendineae were thin and delicate. One of the aortic valve vegetations partly occluded the left coronary ostium. A mass of similar material was impacted, though not firmly adherent, in the left main coronary artery 1 cm. proximal to its bifurcation (fig. 3). There was extensive yellow-brown infarction of the myocardium of the anterior wall of the interventricular septum. The left pulmonary artery contained a thrombus, but there was no infarct of the lung. The spleen weighed 340 Gm. and was about half replaced by dark red infarcts measuring up to 5 cm. in diameter. The kidneys weighed 100 Gm. each and were about three-quarters replaced by infarcts varying from white to dark red in color. Adherent thrombi were found in the renal arteries and veins. Both iliac veins were occluded by adherent thrombi, partly firm and white and partly red and friable. These thrombi extended up the inferior vena cava to the hepatic veins. The liver weighed 1,650 Gm. and was about 5% replaced by white tumor nodules. The adrenals were slightly atrophic. The brain contained an area of gray-tan softening in the frontoparietal area. The other organs were free of major gross lesions.

Microscopically, a papillary cystadenocarcinom of typical ovarian morphology, with a few psammoma bodies, was identified in sections of live lung, and tissues of the pelvis and diaphragm. The verrucous material on the heart valves had the peculiar refractile, deeply eosinophilic, acellular appearance characteristic of verrucous endocarditis

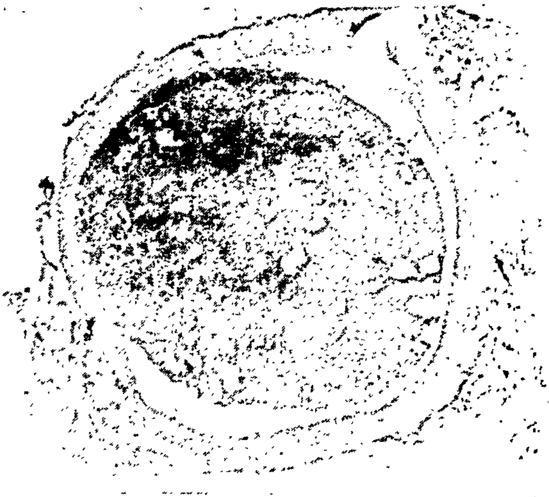

Fig. 3.—Cross section through verrucous embolus *lodge* in left main coronary artery (×10).

It stained the bright blue of collagen with Masson stain (using aniline blue counterstain). The co lagen could readily be distinguished from the re to orange color of the fibrin, which was sometime adherent to it. The verrucous material also had markedly positive reaction to the periodic acid

Schiff test. Where the vegetation arose from the valves there were areas of blending between the valve collagen and the vegetation, and there was an absence of cellular reaction. Emboli having the same tinctorial properties as the verrucae on the heart valves were present in arterial vessels (fig. 4) ranging from arterioles to a major coronary artery and were found in the spleen, pancreas, kidneys, and small intestine as well as the heart. Infarcts varying in age from acute to subacute were present in the heart (fig. 5), spleen, adrenal, kidneys, and brain. True antemortem thrombi were present in the iliac veins and a pulmonary artery. Other positive microscopic findings were slight hyperplasia of the bone marrow and moderate loss of cortical lipid in the adrenals.

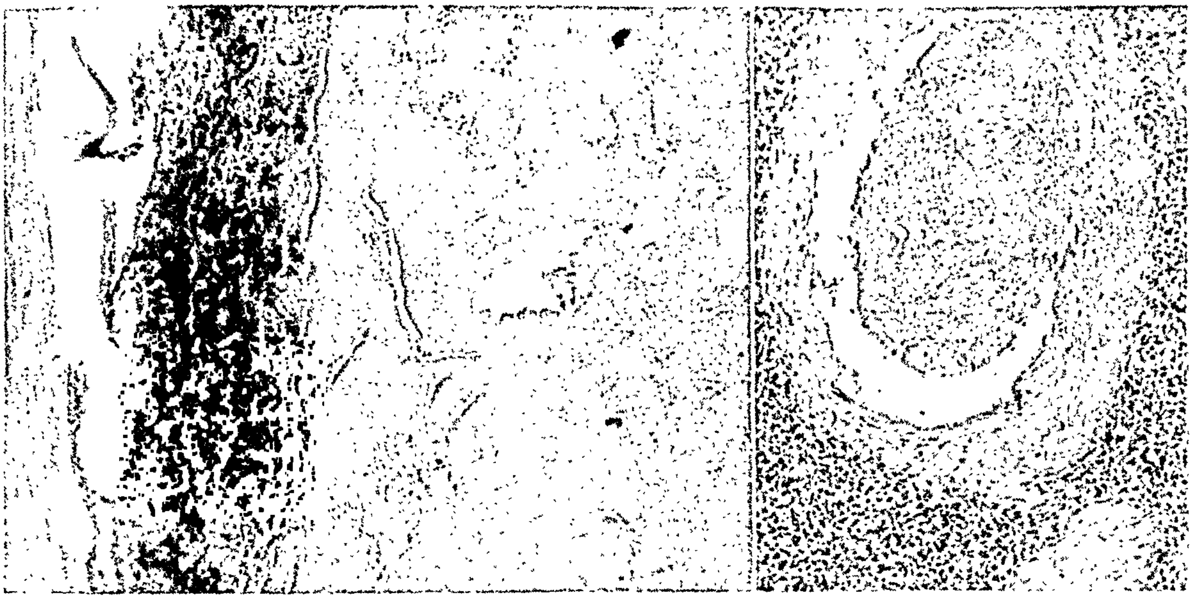

Fig. 4.—*Left*, section of verrucous embolus lying within left main coronary artery (×90). *Right*, verrucous embolus lodged in one of smaller splenic arteries (×50).

Comment

Verrucous endocarditis has been referred to as terminal endocarditis, nonbacterial thrombotic endocarditis, endocarditis simplex, and cachectic endocarditis. Extensive studies by Libman,[7] Gross and Friedberg,[8] and Allen and Sirota [3] have defined this condition as a localized endocardial disease, unrelated to bacterial infection, rheumatic fever, or disseminated lupus erythematosus. Allen and Sirota [3] have suggested that the verrucous excrescences result from degenerative changes in the collagen of the endocardium and heart valves, since the verrucae are argyrophilic and take other stains for collagen. Verrucous endocarditis almost always develops in association with chronic debilitating diseases, such as carcinomatosis, leukemia, tuberculosis, and congestive heart failure. It may, however, occur postoperatively and in other conditions in which a patient's prognosis may be favorable. In the autopsy series reported by Allen and Sirota,[3] 46% of the patients were under 50 years of age. They found that the endocardial lesions were most common in the left side of the heart, especially on the mitral valve. Small verrucae have been recorded as developing from the endothelium of the coronary arteries.

Allen and Sirota have stated, "Occasionally portions of verrucae, particularly of the more friable,

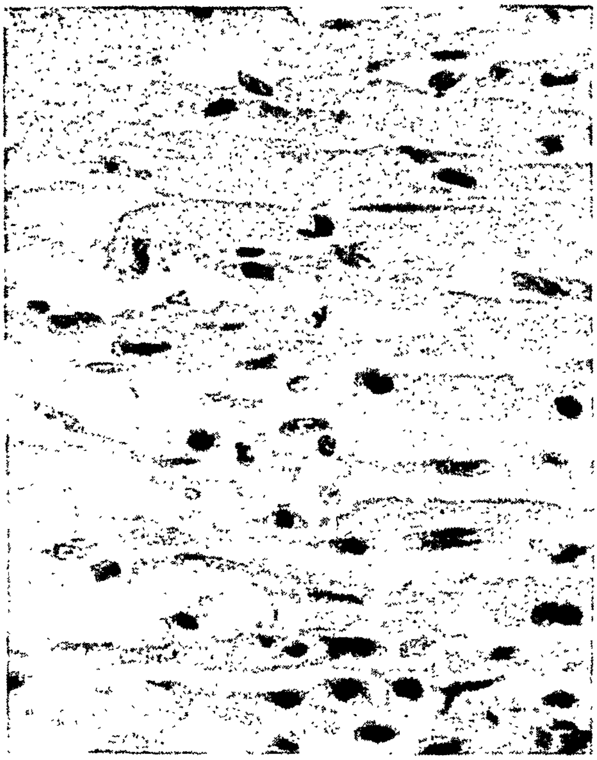

Fig. 5.—Section through myocardium showing recent degeneration of muscle fibers (×240).

exudative type, break off to produce infarcts, and rarely even a fatal encephalomalacia."[3] No cases were specifically cited. The case reported here is the first case, to our knowledge, in which verrucous embolization played such a dominant role clinically. Not only did the patient present a clinical picture and electrocardiographic evidence of a myocardial infarction but there was extensive embolization to the brain, spleen, and kidneys, all of which contributed to the death of this patient.

Summary

Verrucous endocarditis is a fairly common complication of chronic debilitating diseases. In the case described here death was caused by an embolus of verrucous material which arose from an endocardial vegetation, entered a coronary artery, and produced extensive myocardial infarction.

THROMBOEMBOLIC DISEASE IN ADOLESCENCE

Luis M. Ramirez, M.D., Johnson City, N. Y.

Pulmonary heart disease resulting from thrombotic occlusion of the small pulmonary arteries due to repeated "silent emboli" has been recognized for some time. Owen and co-workers[1] have reported 12 cases of this rather rare condition in its purest form, uncomplicated by other serious disease, among 8,000 autopsies within a period of 20 years. The ages of the patients ranged from 32 to 72. According to Parker and Smith,[2] the occurrence of embolic phenomena is unusual before the fourth decade.

In a series of 97 cases of fatal pulmonary embolism reported by Fowler and Bollinger,[3] 81% occurred in the group over 40 years of age, the median age group being 60 to 70.

The case presented here appears to involve one of the youngest patients yet reported with massive pulmonary embolism. A similar case in an 18-year-old athlete has been reported by Neuhof and Klein.[4]

Report of a Case

A 15-year-old boy was admitted to Wilson Memorial Hospital on Aug. 6, 1957. About one month before admission, he had experienced increasing weakness and easy fatigability to the extent that he was unable to perform his usual activities. Two days prior to entry, he had a sudden sharp pleuritic pain in the right lower part of the chest, radiating to the back at the level of the eighth intercostal space; it was aggravated by deep breathing and was accompanied by a hacking, nonproductive cough. There was no hemoptysis, weight loss, or dyspnea. There was anorexia, but without bowel or urinary disturbances. The patient had had an appendectomy at the age of 7, measles and mumps, and a tonsillectomy at the age of 6. There was no evidence of heart disease. He was an enthusiastic baseball catcher and had practiced intensively as such for three years prior to admission.

The patient was slender, well-developed, and somewhat apprehensive, although not in acute distress. Physical examination revealed a body temperature of 101.4 F (38.8 C); pulse, 100 beats per minute; and respirations, 25 per minute. The blood pressure was 120/80 mm. Hg. The throat was not injected. Examination of the heart revealed no cardiac enlargement or murmurs. A few coarse crepitant rales were heard at the base of the right lung. No dulness or increased vocal fremitus was noted at that time. The left lung was normal on auscultation and percussion. The abdomen was soft,

---

From Charles S. Wilson Memorial Hospital.

and neither the spleen nor the liver were palpable. No calf tenderness and no pretibial or ankle edema was elicited. The peripheral pulses were normal. Examination of the blood revealed a hemoglobin level of 13.6 Gm. per 100 cc. and a white blood cell count of 14,300 per cubic millimeter, with 71% neutrophils (4 band forms) and 1 eosinophil. The urine, with a specific gravity of 1.027, was normal. X-ray of the chest was normal.

The patient was put on chloramphenicol (Chloromycetin) therapy with apparent immediate response. On the third hospital day, his temperature was 99 F (37.2 C), the pulse was 88 beats per minute, and the respirations were 23 per minute. He remained afebrile and continued to do well except for occasional cough and slight chest pain on inspiration. On the 10th hospital day, he suddenly developed increasing dyspnea, followed by extreme restlessness and rapid breathing. The patient was now pale, extremely apprehensive, and in considerable distress, perspiring profusely. The temperature was 101 F (38.3 C) and the pulse, 110 beats per minute and regular. Respirations were very shallow, at the rate of 44 per minute. Harsh breath sounds with a prolonged expiratory phase and coarse crepitant rales were heard in the base of both lungs. Examination of the heart revealed sinus tachycardia (rate, 110 beats per minute) but no murmurs. Blood studies revealed a hemoglobin level of 15.5 Gm. per 100 cc., with a hematocrit value of 47%. The white blood cell count was 17,400 per cubic millimeter, with 81% neutrophils, 5 of which were band forms. The sedimentation rate was 0.3 mm. per minute and the carbon dioxide–combining power, 51 vol.%. Another x-ray examination of the chest was normal. The sodium level was 137 mEq. per liter and the potassium level, 3 mEq.; cephalin flocculation was 2+ in 48 hours. The fasting blood sugar level was 104 mg. per 100 cc.; the serum nonprotein nitrogen level, 31 mg. per 100 cc.; and C-reactive protein precipitation, 1+. No L. E. cells were found in the peripheral blood. Agglutination tests for Brucella, typhoid, and paratyphoid were negative. The heterophil antibody was positive in a dilution of 1 to 28. A lumbar puncture revealed normal spinal fluid dynamics, with 4 lymphocytes per cubic millimeter. The spinal fluid total protein level was 13 mg. per 100 cc.; the sugar level, 94 mg.; and the chloride level, 126 mEq. The tuberculin test (PPD) was negative in 24 to 48 hours.

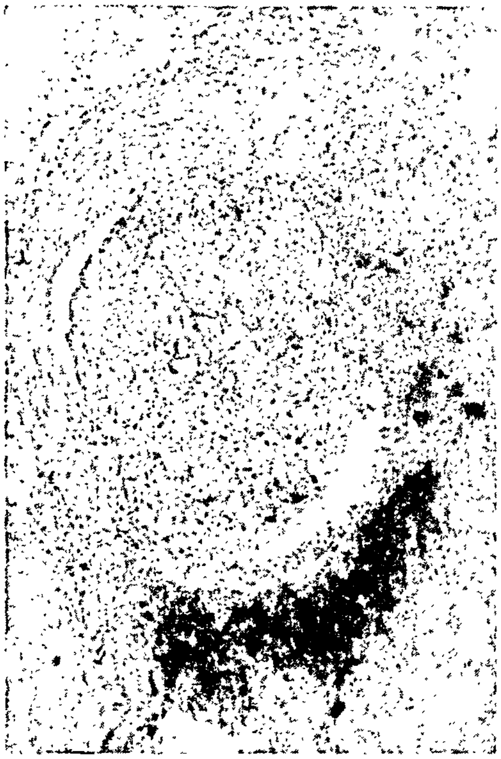
On the next day, the patient complained of joint pains, especially in both knees, the left elbow, and left ankle. An effusion of the left knee joint was noted, as well as swelling of the left elbow and left ankle. All these joints were moderately tender on palpation and motion. A suggestion of a pleural friction rub was detected in the left axillary region. All previous medication was discontinued and antihistaminics were administered, with gradual subsidence of joint symptoms. The patient continued to have a remittent irregular fever, with temperature ranging from 100 to 103.4 F (37.8 to 39.6 C), and frequent unexpected episodes of shallow, rapid respiration, followed by extreme restlessness and mental confusion. Because of suspected personality changes, the patient's increasing apprehension, and frequent episodes of hyperventilation, he was interviewed by a psychiatrist. The patient was found to be intelligent, with a well-integrated personality and without any strong neurotic trends. On the 15th hospital day, there was a sudden onset of sharp pleuritic pain in the left side of the chest, just below the nipple, followed by a persistent productive cough and expectoration of blood-tinged sputum.

The patient was dyspneic, acutely ill, and perspiring profusely. There was definite cyanosis of the fingernails and toenails but no clubbing. A rapid loss of weight had occurred. The temperature was 103 F (39.4 C) and the pulse, 115 beats per minute; respirations were 46 per minute. Examination of the chest revealed diminished breath sounds in the base of the left lung and a pleural friction rub in the lower part of the right lung. The abdomen was soft. Moderate tenderness was elicited in the right upper quadrant of the abdomen, and the left costovertebral angle was markedly tender on Murphy's percussion. Homans' sign was not present. Blood studies showed a hemoglobin level of 10.9 Gm. per 100 cc. and a white blood cell count of 13,900 per cubic millimeter, with 76% neutrophils (56% mature and 20% band forms), 23% lymphocytes, and 1% eosinophils. The urine was cloudy, with a trace of albumin. The erythrocyte sedimentation rate was 0.5 mm. per minute and the carbon dioxide–combining power, 68 vol.%. The serum sodium level was 132 mEq. per 100 cc., the potassium level, 3.2 mEq.; and the chloride level, 105 mEq. The total serum protein level was 6.9 Gm. per 100 cc., with 3.8 Gm. of albumin and 3.1 Gm. of globulin. The guaiac test on stools was 1+. Repeated blood cultures were sterile. A throat culture grew numerous colonies of Diplococcus pneumoniae and Staphylococcus aureus. Culture of the sputum grew Pseudomonas aeruginosa (Bacillus pyocyaneus) in pure culture. No acid-fast bacilli or fungi were found. X-ray of the chest now disclosed pleural effusion on the left and an infiltration in the base of the right lung compatible with a pneumonic process. An electrocardiogram was interpreted as in keeping with left ventricular hypertrophy and sinus tachycardia (rate, 150 beats per minute). Result of a skin test for histoplasmosis was negative.

On the 21st hospital day, the patient's condition deteriorated and his temperature rose to 104 F (40 C). On examination of the chest there were harsh respiratory sounds and coarse crepitant rales in the base of both lungs. The heart rate was 160 beats per minute and regular. The liver was palpable 2 fingerbreadths below the right costal margin. Digitalis and massive doses of several antibiotics were administered without any response.

One thousand cubic centimeters of blood were transfused, after which the hemoglobin level was 9.7 Gm. per 100 cc. The platelet count was 200,000 per cubic millimeter, and the leukocyte count was 24,750, with 90% neutrophils (including 22 band forms). A bone marrow aspiration, smear, and culture were reported as normal. No tumor cells were found in the sputum.

On the 24th hospital day, the patient suddenly developed increasingly severe dyspnea and cyanosis. The blood pressure was unobtainable and the pulse became thready, at a rate of 160 beats per minute. Respirations were gasping, at 50 per minute. He then lapsed into coma, stiffened up in bed, and died at 10:25 a. m.



Section from urinary bladder showing organized thrombus partially attached to venous intima by proliferative endothelium (×250).

Autopsy Findings.—At autopsy, the parietal pleura on both sides was dull and congested and the lower lobe of the left lung was covered by fibrin. The heart weighed 310 Gm. The right atrium was slightly dilated, as was the right ventricle, where many antemortem clots ranging in size from 0.5 to 1.5 cm. were imbedded between the muscle columns. The underlying endocardium did not appear thickened. Sections of the ventricles revealed no grossly visible disease of the myocardium. The valves and coronary arteries appeared to be normal. The lungs were relatively heavy, the right lung weighing 720 Gm. and the left 710 Gm. Large granular brownish-red clots filled the branches of the pulmonary arteries of both lungs, and a cylindrical embolus, about 7 by 0.6 cm., lay free in the left pulmonary artery. The lower lobe of the right lung was enlarged, dark red, and covered by a thin film of fibrin. The middle and upper lobes of the right lung were still air-containing and light pink in color. Multiple sections of the lower lobe of the right lung revealed oozing dark-red surfaces. The left lung showed an area of infarction in the lower segment of the upper lobe. The lower lobe was completely solidified and dark red in color; it sank in water. Multiple sections of the lower lobe of the left lung appeared essentially similar to those of the lower lobe of the right lung. No abnormality was seen in the airways. In the midportion of the left kidney there was an area of recent infarction, 1 cm. long by 0.2 cm. wide, yellowish in color. Milking of the lower extremities while observing the exodus at the inferior vena cava failed to produce any movable clots.

Microscopic examination of the lungs revealed organized clots in the branches of the pulmonary arteries that were adherent to the intima of the vessels and exhibited fibrous tissue proliferation in continuity with the intimal layers. The presence of organized fibrin and fibroblast proliferation implied that some of the clots had been in situ for several days. Organized clots without mural attachment lay within the pulmonary arterioles in areas of widespread infarction. Several blocks showed infarcted lung tissue. The myocardium of the left ventricle was histologically normal. In the wall of the right ventricle there was a mural thrombus in situ without demonstrable attachment to the endocardium. The perivesical and intramural veins of the urinary bladder contained organized thrombi partially attached to the venous intima by proliferative endothelium (see figure). The prostatic venous plexus was extensively involved microscopically by thrombus formation. One large vein showed a recent thrombus of the same structure as those found in the lungs and right heart. Other veins exhibited organized fibrous obliteration with recanalization. The kidney exhibited foci of interstitial hemorrhage and areas of recent infarction.

Comment

Serious or fatal pulmonary emboli may arise from the venous system of apparently normal adolescents and may be the first manifestation of asymptomatic phlebothrombosis.

Although the underlying cause of phlebothrombosis still remains obscure, Crane[5] has postulated that sudden and repeated muscular efforts and strains may in some individuals cause thrombosis of the deep lower leg veins and, in turn, of the pelvic veins. Prolonged dependency stasis, imposed by airplane flights, automobile rides, and even attendance at the theater, has been known to induce thrombosis of this sort, as reported by Homans.[6]

In the present case, some of the emboli apparently originated from the prostatic venous plexus, a rather common site of origin. In 147 cases of pulmonary emboli Moran[7] encountered 44 (29.9%) arising from the prostatic venous plexus.

The symptoms and signs of pelvic venous thrombosis are rather vague and seldom adequately evaluated, as DeTakats and Fowler[8] have shown. They may, however, include pain and swelling of the buttocks or in the abductor muscles close to the inguinal fold, associated with sciatic neuritis, frequency of urination, and mucous diarrhea, or slight suprapubic edema and palpable cords lateral to the prostate or uterus, although none of these criteria were observed in this case.

The manifestations of pulmonary embolism are exceedingly varied and have a definite tendency to recur.[9] Dyspnea is one of the most prominent symptoms. In the present case dyspnea was of sudden onset and rapidly progressed to gasping respirations resembling intermittent episodes of hyperventilation accompanied by extreme restlessness. Mental confusion, marked apprehension, and fright were conspicuous to the extent that a psychiatric consultation was requested. Savacool and Charr[10] reported 12 cases of pulmonary thrombosis in which mental confusion, presumably attributable to cerebral ischemia, was most striking. Other predominant symptoms in the present case were fever, cyanosis, chest pain, tachycardia, anemia, and rapidly progressing signs of right heart failure.

Summary

In a fatal case of multiple pulmonary embolism in a 15-year-old boy, intensive and prolonged physical exertion appeared as the etiological factor. Frequent episodes of hyperventilation were observed.

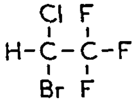
COUNCIL ON DRUGS

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based upon available evidence and do not in any case imply endorsement by the Council.

H. D. Kautz, M.D., *Secretary.*

Halothane (Fluothane).—2-Bromo-2-chloro-1,1,1-trifluoroethane.—The structural formula of halothane may be represented as follows:



$$\begin{array}{ccccc} & & Cl & & F \\ & & | & & | \\ H & - & C & - & C - F \\ & & | & & | \\ & & Br & & F \end{array}$$

Actions and Uses.—Halothane, a volatile, noninflammable liquid, is a general anesthetic agent. Its potency, based on maintenance concentrations of inhaled vapor, is variously estimated as four times that of ether and one-half to twice that of chloroform. The high potency of halothane, which is the basis of many of its desirable properties as an anesthetic agent, is at the same time a serious hazard, necessitating the greatest care and precision in its use. It should be administered only by thoroughly trained individuals who are familiar with its pharmacology and toxic potentialities and with the techniques indicated for its administration.

Induction with halothane is smooth and rapid. Vapors of anesthetic concentration are not unpleasant to most patients and do not irritate the mucous membranes. Halothane depresses, rather than stimulates, salivary and mucous secretions. Sensory depression in the first stage of induction is rather poor. A brief period of excitement is not infrequent, particularly if premedication is light, but is less troublesome than that produced by most other inhalation anesthetics. Complications during induction such as coughing, laryngospasm, bronchospasm, and vomiting are uncommon. When halothane is used for induction, surgical anesthesia is usually achieved in 2 to 10 minutes. The pharyngeal and laryngeal reflexes are obtunded very early, and the relaxation of the jaw is excellent. Therefore, endotracheal intubation may often be done without the use of relaxants, even under very light anesthesia. However, the rapid reversibility of halothane anesthesia requires that the intubation be accomplished swiftly.

Some degree of hypotension occurs in most patients during anesthesia with halothane and constitutes one of the major limiting factors in its use. The blood pressure is lowest during the induction period; during surgical anesthesia it may return to normal but usually stabilizes at a level still somewhat below preinduction values. The degree of hypotension seems to be proportional to the concentration of the vapor in the inspired mixture; sudden increases in this concentration often precipitate a profound fall in blood pressure. Similarly, increasingly severe hypotension may attend attempts to reach lower planes of anesthesia. The mechanism by which this hypotension is produced is unknown. The appearance of the skin, which is dry, warm, and pink, and with distended veins, suggests peripheral vasodilation. Considerable evidence has been adduced in support of a ganglionic blocking effect, but this is not universally acccepted. Evidence concerning other proposed mechanisms is also conflicting or inadequate.

Halothane not infrequently produces alterations of cardiac rate and rhythm. The most common of these is bradycardia; this, in some patients, may be quite marked; heart rates as low as 30 per minute have been reported. Fortunately, this complication can usually be prevented by the prior administration of adequate doses of atropine or other anticholinergic agents. Other disturbances that have been reported include atrioventricular nodal rhythm, atrioventricular dissociation, shifting pacemaker, extrasystoles of ventricular origin, bigeminal and trigeminal rhythms, and cardiac arrest. Deeper levels of anesthesia are associated with a higher incidence and greater severity of these reactions.

Like cyclopropane and chloroform, halothane unquestionably sensitizes the myocardium to the action of epinephrine and levarterenol. Injection of these amines during halothane anesthesia may induce ventricular tachycardia or fibrillation. On the other hand, no serious arrhythmias have accompanied the use of phenylephrine, methamphetamine, or methoxamine. There is some evidence from animal experiments that halothane decreases the force of ventricular contraction. Whether this occurs during halothane anesthesia in human patients is unknown. It seems unlikely, at least, that halothane produces the profound depression often seen with chloroform.

Halothane often causes a diminution in respiratory minute volume. This depression becomes progressively more severe as anesthesia is deepened. Respiratory movements are typically quite shallow, whereas the rate may be either increased or decreased. A pronounced tachypnea has been reported. At levels of anesthesia below the second plane, many patients require respiratory assistance. Completely controlled respiration is said to be achieved with unusual ease.

As with ether, and unlike the situation prevailing with use of chloroform, the circulation usually remains functional at the point at which complete respiratory paralysis occurs. The blood pressure is usually adequate, and the heart may continue to beat for several minutes after respirations cease. Consequently, in such cases, discontinuance of halothane anesthesia and administration of oxygen by artificial respiration is ordinarily followed by rapid lightening of the level of anesthesia and resumption of spontaneous respiratory activity.

Even at very shallow levels of anesthesia, halothane inhibits both the painless uterine contractions of late pregnancy and the contractions during labor, whether spontaneous or induced by oxytocics. The effect has been compared to that of deep ether anesthesia. Severe hemorrhage that has occurred during cesarean sections performed under halothane anesthesia may possibly be due to this effect on uterine tone.

Muscular relaxation in halothane anesthesia is only moderately good. Since the depth of anesthesia is limited by the effects of halothane on the heart and circulation, a skeletal muscle relaxant must often be used as an adjuvant in operations on the upper abdomen or when the peritoneal cavity is to be opened. Succinylcholine, decamethonium, and gallamine have been satisfactory for this purpose. Gallamine possesses the added theoretical advantage of inhibiting the action of the cardiac vagus and thus may help to minimize the bradycardia produced by halothane. Tubocurarine, on the other hand, has produced profound and irreversible hypotension in animals anesthetized with halothane; therefore, tubocurarine probably should not be employed in human patients until further studies clearly establish its safety.

A number of other drugs have been associated with unusual and undesirable effects when given during halothane anesthesia. Since these effects have been noted in only single or, at most, a few instances, and since surgical procedures themselves may modify response to drugs, it is uncertain that halothane is responsible for the modified response. Nevertheless, the following observations seem pertinent. Unusual sensitivity to the hypotensive effect of hexamethonium was reported; an adequate blood pressure was difficult to maintain in a patient who had been taking reserpine; chlorpromazine given postoperatively to control shivering was followed by a sharp fall in blood pressure. These three observations, together with the known propensity of halothane to cause hypotension, enjoin caution in the use of hypotensive agents in conjunction with this agent. Increased sensitivity of a diabetic to insulin after halothane anesthesia has also been reported.

The rapidity of recovery from halothane anesthesia is one of the most valuable attributes of the drug. Reflexes begin to reappear within two minutes and spontaneous movements within five minutes. The incidence of vomiting, which occurs in about 5% of patients in the immediate postoperative period, is unusually low. With proper dosage there is no prolonged period of postoperative hypotension. Intense shivering, apparently associated with a rather pronounced fall in body temperature, is a fairly common occurrence.

Because of its chemical structure, that of a halogenated hydrocarbon, early investigators feared that halothane would have deleterious effects on the liver, similar to those produced by chloroform. To date, however, no reports of serious or permanent hepatic damage have appeared. Liver function tests indicate that halothane, like other anesthetic agents, may produce a temporary depression of hepatic function, but that this effect is transitory, and return to normal usually occurs within a week. The incidence and severity of the hepatic depression is comparable to that produced by ether or cyclopropane. Although histological studies in animals have revealed minimal depletion of glycogen and mild fatty changes, necrosis or other severe morphologic changes have not been detected.

Neither histological studies nor renal function tests have revealed any serious untoward effect on the kidney.

The administration of halothane should be restricted to qualified anesthesiologists. It should be employed only in carefully selected cases and should not be regarded as a general-purpose substitute for ether, cyclopropane, or other standard anesthetic agents. The use of halothane in operations requiring a considerable degree of muscular relaxation is illogical, since its relaxant effect is poorer than that of ether and no better than that of a number of other less hazardous anesthetic agents. Halothane should not be used in the presence of shock, severely diminished cardiac reserve, serious cardiac arrhythmias, or when injection of epinephrine or levarterenol is contemplated. Its use in obstetrics for normal or cesarean deliveries is accompanied by the danger of uterine relaxation and increased bleeding.

The noninflammability of halothane may render it especially useful when electrocautery is used and when diagnostic radiological procedures are carried out. In thoracic surgery, the ease with which controlled respiration can be instituted and its depression of secretions and lack of irritation of the mucosa may be regarded as desirable properties. Lack of elevation of the cerebrospinal fluid pressure and cerebrovenous pressure during halothane anesthesia may indicate its choice for certain neurosurgical procedures.

Dosage.—Halothane is given by inhalation. The extreme potency of the agent and the rapidity with which it produces changes in the level of anesthesia make it essential to exercise extreme care in administration. Unusually swift and accurate appraisals of the clinical signs of the depth of anesthesia must be made as a basis for controlling the concentration of halothane being inspired by the patient. Signs of anesthesia with halothane resemble those with ether, but the successive stages are traversed much more rapidly. Moreover, the pupils constrict early in, and remain constricted throughout, the stage of surgical anesthesia.

Halothane has been administered successfully by a number of techniques: semiclosed, with circle or to-and-fro carbon dioxide absorption; direct flow, without carbon dioxide absorption; and direct flow, nonrebreathing. If sufficient care is taken, halothane can be given by the open-drop method for the induction of anesthesia in children; this, however, is not a preferred method of administration. Difficulty has been reported with the completely closed circuit with carbon dioxide absorption, presumably because of the impossibility of estimating the concentration of halothane being inhaled at a given moment.

The controls provided by conventional ether vaporizers are frequently too coarse to provide sufficiently fine gradations in the amount of vapor delivered. Special vaporizers are now available, with highly accurate settings or calibrations designed to deliver constant concentrations in the presence of variable conditions of temperature, agitation of the vaporizer, changing fluid levels, and varying rates of flow.

Halothane itself, alone or in conjunction with nitrous oxide, may be used for induction. Concentrations of 2 to 2.5% vaporized by a flow of oxygen or nitrous oxide–oxygen mixtures are usually sufficient. A relatively high proportion of nitrous oxide in the mixture is favored by some anesthesiologists for the purpose of improving the analgesia in very light anesthesia. If preferred, however, other conventional agents, such as thiopental or nitrous oxide–oxygen (without halothane) may be used.

Once surgical anesthesia has been achieved, concentrations of 0.5 to 1.5% halothane are sufficient for maintenance.

Premedication before halothane anesthesia need not differ significantly from that used with other inhalation anesthetics. It is especially important, however, that an anticholinergic drug, such as atropine, be included to prevent or minimize bradycardia, which is a frequent concomitant of halothane anesthesia. If atropine is replaced by scopolamine, it should be remembered that the latter has only one-half the activity of atropine on the cardiac vagus.

Preparations.—liquid (inhalant) 125 cc.

Year of introduction: 1956.

Ayerst Laboratories, Division of American Home Products Corporation, cooperated by furnishing scientific data to aid in the evaluation of halothane.

INBORN ERRORS OF METABOLISM

THE influence of genetic make-up on the occurrence of human disease has been familiar to physicians from earliest times. Knowledge regarding the manner in which such influences operate has been available only more recently. The concept of "inborn errors of metabolism" was introduced by Sir Archibald Garrod in 1908.[1] He dealt with four specific metabolic disorders—albinism, alkaptonuria, cystinuria, and pentosuria.

His uncanny prediction that products excreted in these diseases were in reality normal metabolites which accumulated because of deficiency of enzymes responsible for further metabolism has been amply confirmed in recent years. The few diseases studied by Garrod were long considered medical rarities of esoteric interest. With the unraveling of the mysteries of intermediary metabolism, these diseases assumed new importance and have indeed aided in the comprehension of metabolic pathways. The excretion of homogentisic acid in alkaptonuria and 1-xylulose in pentosuria were of immeasurable help in delineating the metabolism of the aromatic amino acids and contributing to the understanding of carbohydrate metabolism. As more modern enzymatic techniques have become available, direct demonstration of enzymatic deficiencies has become possible.

Since Garrod's original contributions many other diseases have been added to the ever-growing list of "inborn errors of metabolism." Taken together they no longer represent medical rarities.

The concept of inherited metabolic abnormalities has been broadened in recent years. The finding by Pauling and associates[2] that the hemoglobin of patients with sickle-cell disease differs from normal adult hemoglobin opened a whole new field of understanding of human disease. Subsequent studies[3] have established that hemoglobin of different persons differs chemically with respect to the presence of a particular amino acid at specific locations in the polypeptide chain. It is apparent that genetic variation may result in the synthesis of proteins closely related to normal but varying in critical detail. Changes in such detail may vastly alter biological function. The apparent absence of a given enzyme may be due, in fact, to the synthesis of an abnormal molecule which lacks enzyme activity.

Many of the metabolic abnormalities appear to be recessive characteristics, thus the full expression of the disease occurs only in homozygotes. Of great interest, however, has been the recent demonstration of many examples of partial expression of some metabolic defects in some heterozygotes. For example, it is known that heterozygotes have about 40% hemoglobin S (sickle-cell hemoglobin) in their erythrocytes. The finding of partial expression in heterozygotes opens up new possibilities that genetic variation may account for more subtle individual metabolic differences.

The metabolic anomalies studied by Garrod were of such a nature as to be detectable from the time of birth. It is, however, apparent that other heritable defects may become manifest only later in life. Typical of such a disease is diabetes mellitus. Evidence for the heritable nature of this disease has been available for many years. There is yet no explanation for the nature of the metabolic defect which permits this disorder to appear at variable ages. There is reason to believe that some metabolic abnormality occurs before the more familiar manifestations of the disease appear.

That a heritable defect resulting in a metabolic abnormality may only become evident after an elapse of time has profound medical implications. It is possible that other diseases have a similar underlying etiology.

It is now obvious that the concept of inborn errors of metabolism is of importance far beyond a few rare syndromes. Further research in enzymology and human genetics will undoubtedly result in rich rewards in the understanding of human disease.

MEDICINE AND THE LAW

OPINION OF THE JUDICIAL COUNCIL

The Judicial Council has authorized the publication of the following opinion.

Question: The 1946 report of the Judicial Council states, in part, that "The division of income given to members of a group practicing jointly or in a partnership must be in proportion to the value of the services contributed by each individual participant." The 1947 report of the Council states, "Since the principles of ethics for private practice absolutely forbid the splitting of fees under any and all circumstances, the same rule applies to group practice; and the group formed must be a real partnership in which the total income is divided not equally but according to the individual income earned by the member." Do these reports mean that only the medical services rendered by a member of a group or partnership may be considered in arriving at the amount payable to each participant?

Answer: In order to clarify its position with respect to the division of group or partnership income the Judicial Council approves and publishes the following rephrasing of its 1946 and 1947 reports on this subject:

> The division of income among members of a group, practicing jointly or in partnership, may be determined by the members of the group and may be based on the value of the professional medical services performed by the member and his other services and contributions to the group.

GOVERNMENT SERVICES

AIR FORCE

School of Aviation Medicine Moved.—The Air Force School of Aviation Medicine moved in July from Randolph Air Force Base, northeast of San Antonio, Texas, to new quarters at Brooks Air Force Base, on the southern edge of the city. This is the second time in its 41-year history that the school has moved to Brooks. More than 33 years ago the school moved there from Mitchell Field, Long Island. Of the seven structures comprising the new facility, five are strictly for aerospace medicine research and instruction. The largest of these is the four-story centrally located Research Institute Building. Conveniently close are the Research Laboratory Shops, Altitude Laboratory, Academic Building, and Flight Medicine Laboratory. To the rear of the group are the heating and cooling plants. The move was incomplete, and priority projects now under way will keep a portion of the school's department of physiology-biophysics at Randolph until winter.

The most outstanding improvement Brooks has over the Randolph facilities is vastly increased classroom space in the academic building. At Randolph the school had six classrooms with a total seating capacity of 279. The Brooks school will have 16 modern, fully equipped classrooms with seats for 735 students, plus a 433-seat assembly hall. In addition it will be partially equipped with closed-circuit television. In connection with these expanded educational facilities, some of the courses previously offered at the Gunter Air Force Base, Ala., branch of the school will be transferred to Brooks. The flight nursing course, six weeks in length and with a total of about 330 students each year, is one of these. All told, the School of Aviation Medicine at Brooks will graduate about 950 students each year from its courses.

A special feature of the new school is the shop for making contact lenses—the only one of its kind in the Air Force. The department of biometrics will have an "electronic brain" for quick analysis of complex scientific statistics. The ear, nose, and throat department will have a reverberation chamber, a room that reflects and intensifies sound, which will be used to study the effects of noise on human beings and animals. The department will also have an anachoic chamber, a room which absorbs sound. It is so quiet in this room that a person can hear his own heartbeat. The room will be used for a variety of purposes, including the testing of delicate hearing instruments and the clinical evaluation of patients with hearing difficulties. The department of radiobiology will have a high-level cobalt-60 radiation facility shielded on all sides by about 5 ft. of concrete. Advanced x-ray equipment will be installed in the flight medicine laboratory. The research photography laboratory will have a full-scale motion picture studio with a sound stage, as well as closed circuit television capabilities.

The space medicine division is scheduled to receive a two-man space cabin simulator in October. It will be capable of sustaining two men for up to 30 days without outside help. The second floor of the Research Institute will have small cubicles where researchers and students can study and write in peace and quiet. The institution's 47,000 volume library will also be here. The third floor will house laboratories for pathology, toxicology, space medicine, pharmacology, and radiobiology. Among buildings planned for the future are a library and professional building.

NAVY

Personal.—Rear Adm. James R. Fulton, M. C., U. S. N., was retired in June after 34 years active service. His last assignment prior to retirement was district medical officer, Fourth Naval District.——The following captains of the medical corps were retired on July 1: Benjamin Ahl, O. H. Alexander, R. W. Babione, W. C. Baty Jr., C. E. Bentel, W. L. Berkley, T. D. Boaz, T. J. Carter, R. E. Fielding, J. R. George, J. N. C. Gordon, J. H. L. Heintzelman, L. L. Kenney, H. M. Maveety, L. E. McDonald, R. S. Simpson, P. E. Spangler, G. E. Stahr, W. P. Stephens, C. B. Stringfellow, J. R. Weisser, O. W. Wickstrom, M. R. Wirthlin, O. D. Yarbrough, and C. K. Youngkin.——The following retired captains of the medical corps who had been serving on active duty reverted to inactive status: J. M. Amberson and L. B. Marshall.

VETERANS ADMINISTRATION

Home-Town Medical Program.—New contracts for the fiscal year 1960 have been completed with medical association intermediaries for conduct of the Veterans Administration's home-town medical program in nine states. Because the contracts include provision for direct processing of physicians' billing statements by the VA, instead of through the intermediaries as in the past, the agreements are expected to expedite payment to private physicians involved and result in a saving of government funds. The nationwide home-town program allows veterans with service-connected disabilities to receive medical care at VA expense from nearly 38,000 private physicians of their choice in areas where care at VA outpatient clinics is not available. The states in which the new contracts have been signed with intermediaries—mostly Blue Cross-Blue Shield organizations—are California, Colorado, Hawaii, Michigan, New York, North Carolina, Oregon, Washington, and Wisconsin.

In the other 41 states and in the District of Columbia the program will continue to operate during the coming fiscal year under previous agreements with state medical associations and other arrangements, as it has in the past. On July 1, physicians from the nine states where the intermediary contracts have been signed began sending their bills for the program directly to VA offices, as is done by physicians in the program from other states.

Paper work for the VA home-town medical care program will be reduced substantially by a new system of mechanized record writing that became effective July 1. The new record writing system will also save time for private physicians in the program. Forms to be completed monthly by the doctors have been reduced to two—a report of treatment rendered and the doctor's bill to the VA for his services. Both are designed to make his writing job brief. The name and address of the private physician, the name and adress of the VA office handling the forms, and the name and VA claim number of the veteran receiving treatment will be printed on the forms by VA Addressograph plates. Use of window envelopes will make addressing of envelopes unnecessary.

The doctor also will receive from the VA an annual authorization for treatment for each of his patients in the program, valid for approved treatment during the year as needed. The VA advises doctors participating in the program to mail their treatment reports and billing statements together to the agency promptly at the end of each month. These forms will be machine-processed by a punch-card system at VA regional offices after medical approval.

PUBLIC HEALTH SERVICE

Dr. Anderson Retires.—Dr. Otis L. Anderson retired on July 1 after 30 years of active duty. Since Oct. 1, 1957, Dr. Anderson has been assistant surgeon general for personnel and training. Immediately on his retirement from the Public Health Service he joined the Washington office of the American Medical Association as medical liaison representative. His post in the Public Health Service was filled by Dr. Richard C. Arnold.

Personal.—Dr. Vernon Knight of Vanderbilt University Medical School, Nashville, Tenn., was appointed as head of the clinical research program of the National Institute of Allergy and Infectious Diseases where he will supervise the planning and conduct of patient-centered studies of diseases caused by viruses, bacteria, fungi, protozoa, and parasitic worms. A clinical program in allergy is also envisioned. The clinical research program will stress staphylococcic infections, especially those due to antibiotic-resistant strains.

MEDICAL NEWS

COLORADO

Dr. Hildyard Named Division Head.—Dr. Victor H. Hildyard, of Los Angeles, was appointed assistant professor and head of the division of otolaryngology, department of surgery, University of Colorado School of Medicine, Denver. Dr. Hildyard assumed the position July 1. He has been in the private practice of otology at Los Angeles since 1957, where he was clinical instructor in the specialty at the University of Southern California.

Plan Hospital for Progressive Patient Care.—Plans for the construction of a new 8-million-dollar, multiphased hospital unit for the Sisters of Mercy of Colorado were announced by Sister Mary Miguel, administrator of Mercy Hospital, Denver. The new eight-story 500-bed hospital will occupy the entire city block on the present site of Mercy Hospital at East 16th Avenue and Milwaukee Street. The progressive patient care plan calls for divisions of "intensive," "intermediate," and "convalescent" care as determined by the degree of illness of the patient admitted to the hospital. The seriously ill patient will be placed in an intensive care unit, with a specially trained nurse available. The convalescent care units will enable the patient to move about freely and assist in meeting his own needs. The present south wing of Mercy Hospital will be converted into a 200-bed hospital home for senior citizens, including small apartments for retired couples needing some medical supervision. Facilities will include rehabilitation, occupational therapy, recreational and central dining area for ambulatory guests. Among the innovations to be used in the new project is a system of electronics in the operating rooms and delivery rooms which will monitor each patient undergoing anesthesia. The present Mercy Hospital was begun in 1901.

CONNECTICUT

Fund to Honor Dr. Barker.—The Associates of the Yale Medical Library announce that the nucleus of a book fund was established at the Medical Library to honor Dr. Creighton Barker, New Haven, a member of the associates and a contributor to the library's collections. As a tribute to Dr. Barker, contributions to this fund are invited for which a suitable bookplate will be designed. Checks may be made payable to Yale University and mailed to Dr. Herbert Thoms, Yale Medical Library, 333 Cedar St., New Haven, Conn.

ILLINOIS

Deaths from Suicide.—*The Illinois Health Messenger* for June reported that deaths from suicide numbered almost one per 1,000 of the total deaths in Illinois in 1956, when suicide ranked 11th as a cause of death in the state. No reported deaths from suicide occurred among persons under age 15, but in the age group 15-24 there were 38 suicidal deaths. The age group with the largest total number of deaths from suicide was 45-64. In 1956, suicide in Illinois ranked sixth among the leading causes of death in persons 15-24, fourth in the 25-44 age group, and eighth in the 45-64 age group. Suicide was not among the leading causes of death among persons 65 years and over.

Chicago

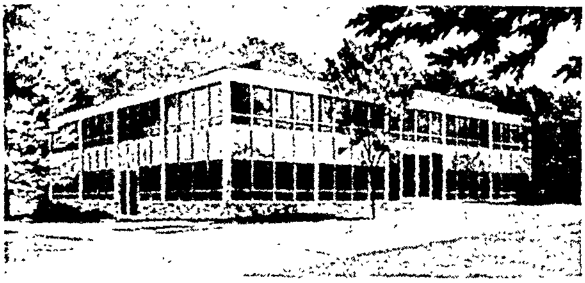
University News.—Dr. George E. Miller, director of house staff education at Buffalo (N. Y.) General Hospital and associate professor of medicine at the University of Buffalo School of Medicine, was appointed to the newly created post of director of research in medical education at the University of Illinois College of Medicine. The new post calls for developing and administering a Commonwealth Fund grant of $112,000 received last November for a two-year pilot study of the process of educating a medical student. The study is expected to result in a permanent center for educational research at the college. Both Dr. Miller's appointment, with the rank of associate professor, and the grant become effective Sept. 1.——Dr. Orville T. Bailey, professor of neuropathology, Indiana University School of Medicine, Indianapolis, was appointed professor of neurology at the University of Illinois College of Medicine. Dr. Bailey succeeded Dr. Percival Bailey, Chicago, not related, who retires from the university Sept. 1. Dr. Orville Bailey is president-elect of the American Association of Neuropathologists and in this capacity was invited to lecture before the British Association of Clinical Pathologists in September.

Dedicate La Rabida Research Center.—Dedication ceremonies for the Richard J. Finnegan Memorial Building, housing the Variety Club Research Center, of the La Rabida Sanitarium were held June 13 and 14. The building, having laboratories

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

equipped with modern chemistry, physics, and biology tools, has a library and conference room available for use by the medical and research staff of the hospital. The upper level of the building is devoted primarily to chemical laboratories including organic, physical, and biochemistry laboratories, and special rooms for instruments and isotope studies. The lower level is devoted to bacteriological experimentation, and includes animal quarters and animal research laboratories. Units are available for experimental pathology, microbiology, and immunology. The ceremonies included a scientific symposium June 13 and a public meeting on rheumatic fever June 14 at which Dr. Aims C. McGuinness, special assistant to the secretary, Health and Medical Affairs, U. S. Department of Health, Education and Welfare, presented the Harry Remer Memorial Lecture. The history of La Rabida began in 1893, when Spain chose a replica of the La Rabida Monastery at Palos for the Columbian Exposition, to commemorate the discovery of America. After the exposition, Spain presented the building to Chicago. In 1896, the Women's Board of La Rabida was formed and took over management of La Rabida. The board has continuously served to provide for sick children in Chicago since that time. At first La Rabida was concerned with the care of infants with diarrheal disease. In 1927, under Dr. Robert A. Black, La Rabida became a sanitarium for children with rheumatic fever. In 1944, when La Rabida became affiliated with the five medical schools of Chicago, clinical care was provided by the respective departments of pediatrics and medical student teaching was introduced. At that time the first board of trustees was organized, with Mr. Samuel Emory Thomason as chairman, who was succeeded on his death by Mr. Richard J. Finnegan. Mr. Finnegan died in 1955. Arrangements began in 1948 for the conversion of the sanitarium to a hospital. In 1949, an affiliation with the University of Chicago for research was inaugurated and in 1950 research laboratories were opened. On July 1, 1957, the La Rabida–University of Chicago Institute was created. The present program covers care for patients up to age 18 with rheumatic fever, rheumatic heart disease, rheumatoid arthritis, allied connective tissue diseases, nephritis, and nephrosis.



Richard J. Finnegan Memorial Building Variety Club Research Center of La Rabida Sanitarium.

Conference on Heart Research.—"Heart Research in Industry" is the title of the seventh annual Heart-in-Industry Conference, which will be held Oct. 16 at the Sherman Hotel, Chicago. The sessions will focus on the significant contribution that industry can make in collaboration with medical science. Among the featured speakers will be Dr. James Watt, director of the National Heart Institute; Dr. Irvine H. Page, director of research, Cleveland Clinic Foundation; and Mr. A. Pope Lancaster, vice-president, manufacturing, Western Electric Company. There will be six workshop discussion groups with panelists representing labor, management, medical research, industrial medicine, and nursing. The conference is jointly sponsored by the Chicago Heart Association and the Association of Commerce and Industry. The conference chairman is Dr. Andrew J. Oberlander, leader of the Industrial Medicine Committee of the Chicago Heart Association, which is responsible for planning the meeting. Reservations should be sent to the Association of Commerce and Industry, 30 W. Monroe St., Chicago 2.

MAINE

State Medical Election.—Officers of the Maine Medical Association for 1959-1960 are: president, Dr. Allan Woodcock, Bangor; president-elect, Dr. Wilson H. McWethy, Augusta; executive director, Dr. Daniel F. Hanley, Brunswick; and secretary-treasurer, Dr. Esther M. Kennard, Brunswick. Dr. Eugene E. O'Donnell, Portland, is immediate past-president. Dr. Carl E. Richards, Alfred, is Council chairman.

MARYLAND

Semiannual Meeting in Ocean City.—On Sept. 18, the Medical and Chirurgical Faculty of the State of Maryland will hold its semiannual meeting in Ocean City, with headquarters at the Commander Hotel. The Council will meet the morning of Sept. 17, and the House of Delegates, the morning of Sept. 18. The speaker at the scientific session will be Dr. Roy Hertz, chief, Endocrinology Branch, National Cancer Institute, Bethesda, who will present, "The Chemotherapy of Hormone Producing Tumors." A dance is planned for the evening of Sept. 18. For information write Mr. John Sargeant, 1211 Cathedral Street, Baltimore 1, Executive Secretary.

MASSACHUSETTS

Dr. Joslin Honored at Doctor-Clergy Dinner.—The first annual Beloved Physicians Award of the Massachusetts Council of Churches was presented to Dr. Elliott P. Joslin, Boston, as the finale to a symposium held April 8 under the sponsorship of the Boston Council of Churches and the Department of Pastoral Services of the Massachusetts Council of Churches. In presenting the award to Dr. Joslin it was stated that "despite the different professional paths taken by physician and minister, both stand together in reverence for life and in awe of death." Dr. Edward D. Churchill, John Homans Professor of Surgery at the Harvard Medical School, represented the medical profession at the symposium and Rev. Samuel Miller, pastor of the Old Cambridge Baptist Church and newly appointed dean of the Harvard Divinity School, represented the clergy at the symposium.

MICHIGAN

Dr. Kramer Resigns.—Dr. Charles G. Kramer, Saginaw, resigned as secretary of the Saginaw County Medical Siciety. Dr. Arthur B. Thompson, of 2144 Ottawa, Saginaw, was appointed as secretary to fill the unexpired term. Dr. Kramer is moving to a different country.

Personal.—On June 18, Dr. James V. Neel, Ann Arbor, received an honorary doctor of science degree from the College of Wooster, Wooster, Ohio. —Dr. Roger B. Nelson, associate director of the University of Michigan Hospital, Detroit, was chosen president-elect of the Michigan Hospital Association which represents about 225 hospitals throughout the state.

Triennial Reunion in Ann Arbor.—The University of Michigan Medical School, Ann Arbor, with over 5,000 living graduates will hold its seventh triennial alumni reunion Oct. 14-17. The program will be chiefly scientific in nature, with clinics, professional exhibits, reports on current medical research, and televised patient demonstrations over a closed-circuit color system. The major nonmedical activity will be the Michigan-Northwestern football game Oct. 17. In addition, there will be class reunions and tours of the university's 8½-million-dollar medical sciences building. The reunion will also help mark the 90th anniversary of the University Hospital, the nation's first to be owned and operated by a university in connection with its own medical school. The last U-M Triennial was held in September, 1956. Dr. John M. Sheldon, Ann Arbor, is chairman of program committee.

MISSOURI

Annual Psychiatric Meeting.—The 12th annual meeting of the Mid-Continent Psychiatric Association will be held Sept. 18-20 at the Holiday Inn Hotel, St. Louis County. Dr. Addison M. Duval, director of the Division of Mental Diseases for Missouri, will address the opening session. Twelve scientific papers will be presented, including the following by out-of-town speakers:

Cerebral Vascular Insufficiency, Dr. Adolph L. Sahs, Iowa City.
Psychological Reactions to Trauma, Dr. Herbert C. Modlin, Topeka, Kan.
Criminal Responsibility, Dr. Manfred S. Guttmacher, Baltimore.
Problems in Classification and Treatment of Depression, Dr. Charles Shagass, Montreal, Quebec.
Therapeutic Problems and Observations of Manic-Depressive Patients, Dr. Joseph B. Parker Jr., Durham, N. C.
Group Psychotherapy in Private Practice, Dr. John J. O'Hearne Jr., Kansas City, Mo.

An early-bird cocktail party will be given Friday evening, Sept. 18. On Saturday afternoon golf, tours, and other events will be available. The annual banquet will be Saturday evening. A program for ladies has been arranged. Nonmembers are cordially invited. For information write Dr. James N. Haddock, 950 Francis Place, Clayton 5, Mo.

NEVADA

Annual Meeting in Reno.—The 56th annual meeting of the Nevada State Medical Association will be held Aug. 19-22, together with the ninth conference of the Reno Surgical Society at the Mapes Hotel, Reno. The Aug. 20 session will be opened with an address by Governor Grant Sawyer, of Nevada. The program includes the following guest speakers: Drs. Donald E. Cassels, Chicago; William Dock, New York; Frank H. Mayfield, Cincinnati, president, Ohio State Medical Association; Michael E. DeBakey, Houston, Texas; Charles P. Larson, College of American Pathologists; Joe Vincent Meigs, Boston; and Hubertus Strughold, Randolph Field, Texas. Panel discussions are planned for the mornings of Aug. 21 and 22, with Dr. John W. Cline, San Francisco, serving as moderator. A banquet is planned for the evening of Aug. 21, with Paul A. Siple, D.Sc., scientific leader, Amundsen-Scott I. G. Y., South Pole Station, Washington, D. C., as the speaker. For information write Mr. Nelson B. Neff, P. O. Box 188, Reno, Nev., executive secretary.

NEW JERSEY

Organize Psychoanalytic Group.—The formation of the New Jersey Psychoanalytic Society, an affiliate of the American Psychoanalytic Association and the International Psychoanalytical Association, was announced at a meeting of the society, June 13. The society, formed April 26, became the 20th affiliate society of the American Psychoanalytic Association. The officers elected at the first meeting of the society May 3 are: president, Dr. Herman Shlionsky, Montclair; vice-president Dr. Raymond H. Gehl, Newark; secretary, Dr. John E. Hughes, Trenton; treasurer, Dr. Samuel A. Weiss, Orange; representative of the executive council of the American Psychoanalytic Association, Dr. Benedict J. Bernstein, Elizabeth; and alternate representative, Dr. Howard H. Schlossman, Englewood. The present mailing address of the society is 377 S. Harrison St., East Orange, N. J.

NEW YORK

Fellowships for Research.—The University of Rochester established a program of postdoctoral fellowships to be awarded graduates of approved medical schools to enable them to pursue research in any of the departments of the School of Medicine and Dentistry. The Buswell Fellowships, made possible by the bequest of the late Mr. Ralph Hochstetter, are intended to assist "well qualified" doctors of medicine to prepare for academic careers. Buswell Junior Fellowships will be awarded to medical graduates who have completed one year of internship or equivalent training. Research experience is not required. Junior fellows are expected to spend about 90% of their time in research or advanced study in preparation for research. Junior fellowships will provide a basic stipend of $4,500 to $6,000 per year, depending on training and experience, and may be renewed with increments for a second or third year. An additional sum of $500 per year may be provided for each dependent. Buswell Senior Fellowships will be awarded to medical graduates who have held a Buswell Junior Fellowship for two or three years or have had comparable experience in medical research and wish to continue in an academic career. Senior fellowships will provide a basic stipend of $5,500 to $8,000 per year, depending upon training and experience, with provision for annual increments. An additional sum of $500 per year may be provided for each dependent. Applications will be received any time. Awards will be announced periodically. A fellowship may be activated at any time during the year after announcement of award. Information and application forms may be obtained from the Chairman, Committee on Buswell Fellowships, Department of Medicine, University of Rochester Medical Center, 260 Crittenden Blvd., Rochester 20, N. Y.

New York City

Paraplegia Researchers Honored.—The Paralyzed Veterans of America, Inc., presented awards to two Columbia-Presbyterian Medical Center physicians, Dr. James B. Campbell and Dr. C. Andrew L. Bassett, for their work in paraplegia, at the 13th annual convention dinner of the PVA, July 22. The two physicians share the 1959 awards with Mr. Harry A. Schweikert Jr., PVA president, who was honored for his "outstanding leadership." Dr. Campbell and Dr. Bassett have been studying the regenerative potential of the severed spinal cord in animals. This research was financed by the Department of the Army, Office of the Surgeon General; National Institutes of Health; the Playtex Park Research Institute; and the United Cerebral Palsy Research and Educational Foundation, Inc. Dr. Campbell is assistant professor of neurosurgery, and Dr. Bassett is assistant professor of orthopedic surgery.

Personal.—Dr. Murray Davidson was appointed director of the department of pediatrics of the Bronx Hospital. He will start his new full-time post Sept. 1. Dr. Davidson also was named associate clinical professor of pediatrics at Albert Einstein College of Medicine.——Dr. George James was named first deputy commissioner of the New York City Department of Health, replacing Dr. Roscoe P. Kandle, who left the department to become commissioner of health of New Jersey. Dr. James has served as a deputy of the health department in charge of planning and research since October, 1956.——The president of Peru, Mr. Manuel Prado, recently conferred the decoration of "Order of the Sun" rank of commander on Dr. George T. Pack, New York surgeon. The ceremony was held in Lima, Peru, on the occasion of the first Peruvian Cancer Congress. The Order of the Sun was founded by General San Martin in 1821.

NORTH CAROLINA

University News.—Dr. Joseph C. Aub, of Boston, delivered the Nathalie Gray Bernard lectures at Bowman Gray School of Medicine, April 30 and May 1, entitled "Cancer and Normal Cell Growth," and "Our Present Study of Cancer Growth." Dr. Aub also spoke at the annual banquet of the Bowman Gray Chapter of Alpha Omega Alpha, April 29. The Nathalie Gray Bernard Lectureship was established by the Bowman Gray faculty in 1942 in honor of Mrs. Bernard, one of the school's chief benefactors.

Annual Conferences on Aging.—The first of four annual conferences on gerontology will be held at Duke University, Durham, Nov. 19-21, under the sponsorship of the university's Center for the Study of Aging. The conference will emphasize basic biological and medical aspects of aging. The program will be built around lectures by some 10 guest speakers from medicine and science. Dr. Ewald W. Busse, director of the Duke Aging Center, noted that the conference is being planned primarily for physicians and persons with special interests in gerontology. The over-all series of four conferences will give equal attention to the biological-medical aspects of aging and to the social and behavioral aspects, with two alternate year meetings on each theme. Major papers and formal discussions of the conferences will be published.

Personal.—Dr. Eben Alexander Jr., professor of neurosurgery, Bowman Gray School of Medicine, Winston-Salem, and chief of professional services, N. C. Baptist Hospital, was reelected president of the United Medical Research Foundation of North Carolina. The foundation, which derives its income from United Funds and Community Chests in North Carolina, has contributed $171,215 to medical research in the state since it was founded four years ago.—Dr. Annie V. Scott, clinical professor of pediatrics, University of North Carolina School of Medicine, was presented with the annual Achievement Award by the Woman's Medical College of Pennsylvania, Philadelphia. The citation received by Dr. Scott reads, in part, "In proud recognition of her distinguished attainments as pediatrician and medical educator in China, where she served as a medical missionary for a large part of her life. . . ."

PENNSYLVANIA

Philadelphia

Dr. Ferguson Named Surgery Chairman.—Dr. Lewis K. Ferguson, professor of surgery, University of Pennsylvania Graduate School of Medicine, was appointed chairman of the department of surgery, effective July 1, succeeding Dr. Herbert R. Hawthorne, who has held the post since 1954. Dr. Hawthorne became an emeritus professor.

Hospital Completes Medical-Science Building.—The Lankenau Hospital had a schedule of events June 4-6 to celebrate completion of its new $4,300,000 Medical-Science Building. Brigadier General Carl W. Tempel, Washington, D. C., addressed a dinner in the hospital June 4. Lankenau's Medical-Science Building, a six-story structure, has three floors which contain 126 private and semiprivate bedrooms for short-term convalescent patients and others undergoing diagnosis or treatment for non-acute conditions. The new building also houses the recently expanded Division of Research, the Health Examination and Diagnostic Service, and an enlarged Physical Therapy Department. An "open house" was held June 6 for the general public.

Diplomat Takes Postgraduate Work.—Dr. Arturo Z. Pellerano, of Ciudad Trujillo, a physician representing the Dominican Republic in Philadelphia as its consul, was accepted for the University of Pennsylvania Graduate School of Medicine for the 1959-1960 school year. He will take courses toward obtaining specialty training in obstetrics and gynecology. Dr. Pellerano was appointed consul in Norfolk, Va., in June, 1957, after serving as medical director of the city hospital in Yabucoa, Puerto Rico. He received his M.D. degree from the University of Santo Domingo (Dominican Republic) School of Medicine in 1948, and completed his internship and residency at Yabucoa Hospital before becoming medical director.

University News.—At the annual meeting of the Hahnemann Medical College and Hospital's board of trustees May 27 Dr. Charles S. Cameron, dean, and Mr. Charles S. Paxson Jr., the hospital's administrator, were elected vice-presidents of the 111-year old Philadelphia institution.—Honorary degrees were presented at Hahnemann Medical College June 12 to Dr. Jonas E. Salk, Commonwealth Professor of Preventive Medicine, University of Pittsburgh; Dr. Stanhope Bayne-Jones, chairman, Secretary's Consultants on Medical Research and Education, U. S. Department of Health, Education and Welfare; and to Detlev W. Bronk, Ph.D., president, Rockefeller Institute for Medical Research. Dr. Bronk delivered the main address during the graduation program.

RHODE ISLAND

Symposium on Athletic Injuries.—The University of Rhode Island will present a symposium on the prevention and treatment of athletic injuries on Aug. 17-18 in Kingston. The symposium will include lectures, panel discussions, and demonstrations, with opportunities for questions and answers and participant discussion. Panel topics are Abdominal, Genitourinary, and Thoracic Injuries, and Conditioning the Player. The university will issue a certificate to all registrants who complete the symposium. Fee for the program is $25. For information and registration, write the University of Rhode Island, Department of Physical Education & Athletics, Kingston, R. I.

TEXAS

Symposium on Problems in Surgery and Medicine.—On Sept. 19, a symposium, "Current Problems in Surgery and Medicine," will be co-sponsored by the Fifth District Chapter of Texas of the American College of Surgeons, the Tenth District Medical Society of Texas, and the Beaumont Academy of Medicine. The meeting will be held at the Hotel Beaumont, in Beaumont. The following papers and speakers are scheduled:

Medical Evaluation of the Preoperative Surgical Patient, Dr. Michael J. Lepore, New York City.
Hysterectomy—*When and Why*, Dr. M. Edward Davis, Chicago.
Management of Severe Trauma of the Chest, Dr. Thomas H. Burford, St. Louis.
Five Year Follow-up of Extended Radical Mastectomy, Dr. Jerome A. Urban, New York City.
Peripheral Endarterectomy, Dr. Jack A. Cannon, Los Angeles.
Office Proctology, Dr. Robert Turell, New York City.

A program of ladies activities is planned. There is no fee for the meeting. For information write Dr. Bedford F. Pace, 555 Tenth St., Beaumont, Texas.

UTAH

New Headquarters for State Association.—Executive offices of the Utah State Medical Association and Salt Lake County Medical Society are occupying a newly remodeled and enlarged headquarters building at 42 S. 5th East. Work started last spring included an extension of the two-story structure, with a new facing of Park City sandstone and a complete revamping of the interior to provide more

[illegible] DEPT.
[illegible]

attractive and commodious quarters. A new feature on the first floor is an enlarged meeting room, with a movable partition and facilities for projecting slides or motion pictures. The second floor includes a new board room office for Mr. Harold Bowman, executive secretary, and other employees. Interior walls have been refinished with walnut paneling, and the structure has been refurnished and carpeted. A new heating and air-conditioning system was installed. Additional parking space in the rear has been installed.

VERMONT

Symposium on Catecholamines.—A symposium, "The Catecholamines in Cardiovascular Pathology," will be held at the University of Vermont College of Medicine, Burlington, Aug. 23-26. This symposium will be subdivided into three sections: (1) pathogenic mechanisms, (2) prophylactic possibilities, (3) rationale of therapeutic procedures. Both fundamental phenomena at the cellular level and clinical implications will be discussed to correlate basic and clinical points of view. Inquiries should be directed to Dr. Wilhelm Raab, Professor of Experimental Medicine, University of Vermont College of Medicine, Burlington, Vt.

VIRGINIA

Appoint Department Chairmen.—Administrative appointments at the Medical College of Virginia, Richmond, were announced by Dr. William F. Maloney, dean. These include professor and chairman of the department of medicine, Dr. William T. Thompson Jr., formerly chief of medicine at McGuire Veterans Administration Hospital, Richmond; professor and chairman of the department of pathology, Dr. George Margolis, formerly professor of pathology at Duke University School of Medicine, Durham, N. C.; professor and chairman of the department of psychiatry, Dr. Robert A. Senescu, formerly assistant clinical professor of psychiatry at Columbia University College of Physicians and Surgeons, New York City.

WEST VIRGINIA

State Convention in White Sulphur Springs.—The 92nd annual meeting of the West Virginia State Medical Association will be held at the Greenbrier, White Sulphur Springs, Aug. 20-22. The presidential address will be given by Dr. George F. Evans, Clarksburg. Governor Cecil H. Underwood will address the first general session the morning of Aug. 20, and Dr. Louis M. Orr, president, American Medical Association will be the guest speaker before the second session of the House of Delegates Aug. 22. Papers to be presented at the general sessions are as follows:

The Physician's Responsibility in the Prevention of Automobile Crash Injuries and Deaths, Dr. Fletcher D. Woodward, Charlottesville.
Abdominal Trauma with Emphasis on Automobile Injuries, Dr. Frederick E. Kredel, Charleston, S. C.
Injury in Sports, Dr. Owen B. Murphy, Lexington, Ky.
The Hyperventilation Syndrome, Dr. William A. Sodeman, dean, Jefferson Medical College, Philadelphia.
Must Time Take Its Toll, Dr. Theodore G. Klumpp, New York City.
The Clinical Diagnosis of Common Viral Diseases, Dr. Fred R. McCrumb Jr., Baltimore.
Habitual Abortion, Dr. Carl T. Javert, New York City.
Accidental Poisoning in Children, Dr. Julian P. Price, Florence, S. C., Vice-Chairman, A. M. A. Board of Trustees.
Radiation Hazards in Diagnostic Roentgenology, Dr. Harold S. Pettit, Charleston, S. C.

Tournaments for golf and trap and skeet shooting are planned. Motion picture sessions and technical and scientific exhibits are arranged. A program of entertainment is scheduled. For information write Mr. Charles Lively, 401 Atlas Building, Charleston, W. Va., executive secretary.

GENERAL

New Journal on Research of Sex.—The Society for the Scientific Study of Sex will publish a new journal, *The Journal of Sexual Research*. The first issue will appear early in 1960. The journal is to include original articles, reviews of the literature, book reviews, and abstracts covering the range of all the learned disciplines pertinent to the study of sex. Papers should be submitted to Hugo G. Beigel, Ph.D., 138 E. 94th St., New York 28.

Psychoanalytic Meeting in New York City.—The semiannual fall meeting of the American Psychoanalytic Association will be held at the Hotel Biltmore, New York City, Dec. 4-6. The program will feature about 25 scientific papers and four major panel symposiums on psychoanalytic aspects of medical practice. For information and reservations, write to the Executive Secretary, 36 W. 44th St., New York 36.

Call for Psychosomatic Papers.—The American Psychosomatic Society will hold its 17th annual meeting at the Sheraton-Mt. Royal Hotel in Montreal, Canada, on Saturday and Sunday, March 26-27, 1960. The program committee would like to receive titles and abstracts of papers for consideration for the program no later than Dec. 1. The time allotted for presentation of each paper will be 10 or 20 minutes. Abstracts, of two or three pages, in nine copies, should be submitted for the program committee's consideration, to the Chairman, Dr. Eric D. Wittkower, at 265 Nassau Road, Roosevelt, N. Y.

Meeting of Anesthesiologists.—The New England Society of Anesthesiologists will hold its second annual conference Sept. 17-19 at the Equinox House, Manchester-in-the-Mountains, Vt., under the theme, "Agents and Techniques." The following speakers will each present two papers: Dr. Paul R. Dumke, Detroit; Dr. Louis R. Orkin, New York City; Dr. Richard G. B. Gilbert, Montreal, Canada; Dr. William S. Howland, New York City; and Dr. Harold R. Griffith, Montreal, Canada. The annual golf tournament will be held the afternoon of Sept. 18, and the annual banquet, the evening of Sept. 19. For information write the New England Society of Anesthesiologists, P. O. Box 81, Kenmore Station, Boston 15.

Radiological Meeting in Denver.—The 21st midsummer radiological conference of the Rocky Mountain Radiological Society will be held Aug. 20-22 at the Hotel Shirley-Savoy, Denver. Dr. George A. Unfug, Pueblo, Colo., president of the society, will present an address at the opening session. The program includes the following guest speakers: Dr. Eugene P. Pendergrass, Philadelphia; Dr. Philip J. Hodes, Philadelphia; Dr. Owings W. Kincaid, Rochester, Minn.; Dr. Franz J. Buschke, San Francisco; and Dr. Magnus I. Smedal, Boston. At the banquet Aug. 21, 7:00 p.m., Dr. Hodes will present "Medical Meddlers; What Price Insecurity." Scientific and technical exhibits are scheduled, and a program of ladies' entertainment is arranged. There is no registration fee. For information write Dr. John H. Freed, 4200 E. Ninth Ave., Denver 20, Secretary-Treasurer.

Society News.—The officers of the American Gastroenterological Association are: president, Dr. H. Marvin Pollard, Ann Arbor, Mich.; president-elect, Dr. Hugh R. Butt, Rochester, Minn.; vice-president, Dr. Franz J. Ingelfinger, Boston; treasurer, Dr. George G. McHardy, New Orleans; and secretary, Dr. Wade Volwiler, Department of Medicine, University of Washington, Seattle 5, Wash. The annual meeting is scheduled for March 31-April 2, 1960, at the Roosevelt Hotel, New Orleans.——The following officers of the **Mid-Central States Orthopaedic Society** were elected in April to serve for the ensuing year: president, Dr. Harvey O. Anderson, Wichita; vice-president, Dr. Daniel L. Yancey, Springfield, Mo.; secretary-treasurer, Dr. Henry O. Marsh, Wichita; and members at large, Drs. Oscar P. Hampton Jr., St. Louis, and Dr. James E. Pollard, Pueblo, Colo.——Officers of the **Western Association of Physicians** are: president, Dr. David A. Rytand, San Francisco; vice-president, Dr. Paul Starr, Los Angeles, and secretary-treasurer, Dr. Wade Volwiler, Seattle.

Congress on Physical Medicine.—The 37th annual meeting of the American Congress of Physical Medicine and Rehabilitation will be held Aug. 30-Sept. 4, in Minneapolis. The American Academy of Physical Medicine and Rehabilitation will meet at the same time in a two-day seminar sponsored by the American Rehabilitation Foundation, a division of the Sister Elizabeth Kenny Foundation. Slated for discussion at the latter meeting are three basic subjects, including the hand and upper extremity, rehabilitation in speech and language, and basic research in the collagenoses. Five main sessions and scientific and technical exhibits will feature the five-day conference by the American Congress of Physical Medicine and Rehabilitation during the same period. Scientific films will deal with the management of muscular dystrophy, vocational status following chemopallidectomy for Parkinson's disease, and rehabilitation of the bilateral upper extremity amputee. Dr. Arthur C. Jones, Portland, Ore., is president of the American congress. He will address the assembly Sept. 2. The John Stanley Coulter lecture will be delivered by Dr. Robert L. Bennett, Warm Springs, Ga. Dr. Louis B. Newman, Chicago, is president of the American Academy of Physical Medicine and will be succeeded by president-elect Clarence W. Dail, Los Angeles. The congress is planning its third international session on physical medicine, to be held in Washington, D. C., the week of Aug. 21, 1960.

Infant Mortality.—The long-term downward trend in infant mortality has come to a halt, it is reported by statisticians of the Metropolitan Life Insurance Company. There were about 113,000 deaths among babies under one year of age in 1958, equivalent to a rate of 26.9 per 1,000 live births. This compares with the rate of 26.4 per 1,000 in 1957 and the all-time low of 26.1 in 1956 reported by the National Office of Vital Statistics. The record of the last two years is in contrast with that of the decade between 1945-1946 and 1955-1956, the statisticians point out. During that period every state, without exception, succeeded in reducing its infant mortality rate. In 31 states and the District of Columbia, the decrease amounted to 25% or more. New Mexico's infant mortality rate fell 56%, and Maine and West Virginia each recorded a reduction of over 40%. All of the major causes of infant mortality, except postnatal asphyxia, showed a decline during the decade ending in 1955-1956. The death rate from the gastrointestinal diseases dropped more than 60%. For whooping cough, the decline was about 75%. Other communicable diseases of childhood—measles, scarlet fever, and diphtheria—have been reduced "to vanishing proportions as causes of death in infancy." The improvement in mortality has been greater in later infancy, the statisticians report. For infants beyond one month of age, the death rate fell 40% between 1945-1946 and 1955-1956. For babies under 4 weeks of age, the decline was little more than 20%. For infants under one day of age, the death rate fell only 12%. Currently nearly two-fifths of all infant deaths occur in the first day of life; 10 years earlier the proportion was one-third.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Area	July 11, 1959		July 12, 1958

Greeting Cards Aid Children.—Special modern greeting cards, UNICEF Greeting Cards, are published by the United Nations Children's Fund to "bring happiness, in the form of improved health and a better chance for survival, to countless needy children in underdeveloped areas of the world." In 1946 a 7-year-old girl was so grateful for the emergency aid she and her fellow school children had received from UNICEF that she tried to express their feelings by sketching a picture on a piece of glass. It was her effort which was to become the first UNICEF card. In 1949, 130,000 cards were purchased by friends of the Children's Fund in the United States. Last year, over 10,500,000 cards were sold in more than 70 countries and territories, half of them in the U. S. A. The profits from a single box of 10 cards priced at $1.25 can provide 45 children with a glass of milk every day for a week. Originally formed to supply emergency foods, mostly milk, to the children of war-torn Europe and Palestine, UNICEF is entirely devoted to the welfare of children and mothers. UNICEF is currently aiding more than 100 countries and territories in medical and nutrition programs, designed to become a permanent part of each country's health service. Each aided country matches the value of UNICEF supplies on an average ratio of more than $2 for each dollar of UNICEF aid. So far, with UNICEF's help, more than 103 million children reportedly have been vaccinated against tuberculosis; over 21 million persons, more than half of them mothers and children, have been cured of yaws; up to 1959, 3.9 million children reportedly had been saved from blindness. Each year, artists have donated their works to be reproduced as UNICEF Greeting Cards. This year they include Joan Miro, Dong Kingman, Jozef Domjan, Bettina, Doris Lee, and Kay Christensen. A descriptive brochure can be had by writing to the U. S. Committee for UNICEF, Greeting Cards, United Nations, N. Y.

Poliomyelitis Conference.—Sponsored jointly by the Pan American Health Organization and the World Health Organization, with the financial assistance of the Sister Kenny Foundation of Minneapolis, the International Conference on Live Poliovirus Vaccines in Washington, D. C., ended its sessions in June. Although the conference strongly urged continued use of the inactivated (Salk) vaccine, the members believe that there is a place for a vaccine that may be of lower cost, simpler to use, and potentially capable of having a greater protective effect on a community basis, specifically a vaccine that can be administered orally. It was recognized, however, that the use of a product that spreads beyond those originally vaccinated represents a radical departure from present practices.

More than 20 field studies were reported from 15 countries. Most of these were carried out in a highly susceptible population that had not been given the Salk vaccine. These studies yielded different results in different environments. For instance, in some studies the number of children who lacked antibodies and to whom the live vaccine had been administered, it was reported as being only 50 to 60% effective, whereas in others it was 90 to 100% effective. The degree of spread of infection to contacts of those vaccinated varied in different situations, but in families and in closed institutions spread was common. It has not been possible to follow clearly the natural spread of attentuated poliovirus after its first or second passage.

Studies of great magnitude involving administration of vaccine on a community-wide basis to hundreds of thousands of persons have been reported from Africa, Asia, Europe, Latin America, and the

USSR. Smaller, and therefore, more carefully controllable studies, have been reported from Europe and the United States. No evidence has been adduced that use of any of the vaccines has been followed by either paralysis or ill-defined illnesses in either group greater in number than have been observed in a control group or in the community at large among nonvaccinated persons. In most of the studies there have been no attempts to assess effectiveness other than by increase in antibodies. In a few instances, however, it has been claimed that use of the vaccine has been followed by low attack rates, either in those vaccinated or in the community, which are consistent with those that might be expected as a sequel to use of an effective vaccine.

CANADA

Duke of Edinburgh Installed.—Gowned in the robes of Chancellor of Edinburgh University, H.R.H. The Prince Philip, Duke of Edinburgh, following his installation as president of the Canadian Medical Association, is shown with representatives from other medical associations. Left to right: Sir Arthur Thomson, Birmingham, England, President, British Medical Association; H.R.H.; Dr. Louis M. Orr, Orlando, Fla., President, American Medical Association; Dr. R. Lemieux, Quebec City, P. Q., President-Elect, World Medical Association; and Dr. Emile Blain, Directeur-Général, L'Association des Médecins de Langue Francaise du Canada, Montreal, P. Q. The installation ceremonies took place at the Royal York Hotel, Toronto, and marked the 92nd annual general meeting of the Canadian Medical Association on June 30.

LATIN AMERICA

Society of Medical Education in Argentina.—The Argentine Society of Medical Education has been formed for the study of problems in medical education, with special and immediate emphasis on (1) the establishment of postgraduate residency systems in federal, municipal, and private hospitals; (2) modernization of the hospital system; (3) creation of specialty accreditation and recognition in the various medical fields, i. e., Argentine boards of internal medicine, boards of surgery, etc.; (4) collaboration with medical, scientific, and educational organizations with similar objectives. All correspondence should be directed to Dr. Jorge Manrique, Secretary, Cuemes 2926, Buenos Aires, Argentina.

FOREIGN

Pediatric Meeting in Budapest.—The Hungarian Pediatric Association will hold its biannual meeting on Nov. 26-29 in Budapest. Subjects will include: (1) Staphylococcus Infections, (2) X-Ray Injuries in Childhood, and (3) Hematological Diseases in Childhood. For particulars apply to Dr. Emil Litvay, Secretary General Péterfy Sándor utca 12, Budapest.

Congress of Gastroenterology.—The sixth meeting of the Association of the National European and Mediterranean Societies of Gastroenterology, organized by the Association of Dutch Gastroenterologists, will be be held in Leiden, the Netherlands, April 20-24, 1960. The main themes of the conference will be (1) pathology of the small intestine and (2) hepatitis, cirrhosis hepatitis, and their possible connection. Panel discussions, lectures and film shows will be arranged in connection with these themes and related subjects. Scientific and technical-commercial exhibits also will be organized. Original reports, either clinical or in the field of the basic sciences, are invited for submission and will be accepted for panel discussion or publication if approved by the scientific program committee. Titles for papers, together with a summary of not more than 200 words, should be sent not later than Aug. 1 to Dr. B. K. Boom, Congress Office, Department of Gastroenterology, University Hospital, Leiden, the Netherlands. The official language is English. Working languages will be English, French, German, and Spanish (with simultaneous translation). Registration fees (including an official reception, a banquet, and an excursion) are: Full members, U. S. $45; accompanying family members U. S. $20. After Nov. 1, the registration fee for full members will be U. S. $55. For information and registration forms, apply to the Congress Office, Sixth Meeting of the Association of the National European and Mediterranean Societies of Gastroenterology, Department of Gastroenterology, University Hospital, Leiden, the Netherlands.

CORRECTION

Football Coach.—Don H. O'Donoghue, M.D., was incorrectly identified in the summary report on the Scientific Assembly of the recent A. M. A. convention (The Journal, July 4, p. 1193) as coach of the University of Oklahoma football team. Dr. O'Donoghue, *an orthopedic surgeon, services* the Oklahoma "Sooners" through his clinic in Oklahoma City.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Various Centers: Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates: Stations around the world, Sept. 22. Final date for filing applications was June 22. Succeeding examinations—March 16, 1960 and Sept. 21, 1960. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 21-23, 1960. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery.

Alaska:* On application in Anchorage or Fairbanks. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Examination.* Phoenix, Oct. 14-16. *Reciprocity.* Phoenix, Oct. 17. Ex. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, Nov. 5-6. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* Los Angeles, Aug. 17-20; Sacramento, October 19-22. *Oral.* Los Angeles, August 15; San Francisco, November 14. *Oral and Clinical.* Los Angeles, August 16; San Francisco, Nov. 15. Sec., Dr. Louis E. Jones, Room 536, 1020 N Street, Sacramento.

Connecticut:* *Homepathic. Examination.* Derby, Sept. 8. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

District of Columbia:* *Examination.* Washington, Dec. 14-15. *Reciprocity.* Washington, Sept. 14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., Washington 6.

Florida:* *Examination.* Miami Beach, Nov. 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, Oct. 13. Sec., Mr. Cecil L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Indiana: *Examination.* Indianapolis, June 1960. *Reciprocity.* Indianapolis, fourth Wednesday of each month. Ex. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Kansas:* *Examination and Reciprocity.* Kansas City, January 1960. Sec., Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

Louisiana: *Examination and Reciprocity.* New Orleans, Dec. 3-5. Sec., Dr. Edwin H. Lawson, 930 Hibernia Bank Bldg., New Orleans 12.

Maryland: *Examination.* Baltimore, Dec. 8-11, Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore 1.

Massachusetts: *Examination and Endorsement.* Boston, July 14-17. Sec., Dr. David W. Wallwork, Room 37, State House, Boston 33.

Montana: *Examination and Reciprocity.* Helena, Oct. 6. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination.* Omaha, June 13-15, 1960. Dir., Bureau of Examining Boards, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada:* *Examination and Reciprocity.* Reno, Sept. 8. Sec., Dr. G. H. Ross, 112 North Curry St., Carson City.

New Hampshire: *Examination and Reciprocity.* Concord, Sept. 9-12. Sec., Dr. Edward W. Colby, 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 20-23, *Reciprocity.* Monthly, Sec., Dr. Royal A. Schaaf, 28 West State St., Trenton.

New Mexico:* *Examination and Reciprocity.* Santa Fe, Nov. 16-17. Sec., Dr. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, Dec. 8-11. Sec., Dr. Stiles D. Ezell, 23 South Pearl St., Albany.

Ohio: *Examination.* Columbus, Dec. 15-17. *Endorsement.* Columbus, Aug. 26 and Oct. 5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Puerto Rico: *Examination.* San Juan, Sept. 8. Sec., Dr. Joaquin Mercado Cruz, Box 9156, Santurce.

South Dakota:* *Examination.* Sioux Falls, Aug. 25-26. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination.* Memphis, Sept. 23-24. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Texas:* *Examination.* Fort Worth, Dec. 3-5. *Reciprocity.* Houston, Aug. 29-31. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Wyoming: *Examination and Reciprocity.* Cheyenne, Oct. 5. Sec., Dr. James W. Sampson, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: *Examination and Reciprocity.* Juneau, November. Sec., Dr. R. Harrison Leer, Alaska Office Bldg., Juneau.

Arizona: *Examination.* Tucson, Sept. 15. Sec., Mr. Herman E. Bateman, University of Arizona, Tucson.

Colorado: *Examination.* Denver, Sept. 2-3. *Reciprocity.* Denver, Sept. 4. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: *Examination.* New Haven, Oct. 10. Exec. Asst., Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

District of Columbia: *Examination.* Washington, Nov. 23-24. *Reciprocity.* Washington, Sept. 14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., Washington 6.

Kansas: *Examination.* Pittsburg, Nov. 6-7. Sec., Dr. Leon C. Heckert, Kansas State College, Pittsburg.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 9-10. Sec., Mrs. Anne Baker, West Michigan Ave., 116 Stevens T. Mason Bldg., Lansing.

Minnesota: *Examination.* Minneapolis, Oct. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Oklahoma: *Examination.* Oklahoma City, Sept. 25-26. Exec. Sec., Mrs. L. Haidek, 813 Braniff Bldg., Oklahoma City.

South Dakota: *Examination.* Vermillion, Dec. 4-5. Dr. Gregg M. Evans, 310 East 15th St., Yankton.

Texas: *Examination.* Austin, Oct. 12-13. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 11 and Milwaukee, Dec. 5, Sec., Mr. Wm. H. Barber, 621 Ranson St., Milwaukee.

---

*Basic Science Certificate required.

DEATHS

Appell, Paul Harry Ⓜ Bristol, Conn.; University and Bellevue Hospital Medical College, New York City, 1923; associated with Bristol Hospital, where he served as secretary-treasurer, vice-president, and president of the medical staff, and chief of the pediatric service; died in Farmington May 20, aged 59.

Bergstein, David Ⓜ New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1920; member of the American Academy of General Practice; died while vacationing in Miami Beach, Fla., March 31, aged 64.

Bittner, Linus Herman Ⓜ Glendale, Calif.; University of Oregon Medical School, Portland, 1919; veteran of World War I; formerly a Methodist missionary in Indonesia; served on the staff of the Memorial Hospital of Glendale; died in Acton May 23, aged 69.

Bowman, Lang Fulton Ⓜ Wichita, Kan.; Rush Medical College, Chicago, 1915; served as county coroner; veteran of World War I; died in the Veterans Administration Center May 23, aged 74.

Bridenbaugh, Charles Sumner Ⓜ Emlenton, Pa.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1903; past-president of the Venango County Medical Society; served as school physician and for many years on the school board; for many years physician for the Selective Service Board; associated with the Franklin (Pa.) Hospital, where he died May 22, aged 79.

Bulkley, Kenneth Ⓜ St. Paul, Minn.; Columbia University College of Physicians and Surgeons, New York City, 1909; service with the Veterans Administration terminated Feb. 19, 1959; died in Glendale April 16, aged 74.

Caplan, Isidor, New York City; Cornell University Medical College, New York City, 1909; died April 13, aged 71.

Carpenter, William Bowers, Sunbury, Ohio; Starling Medical College, Columbus, 1903; died May 23, aged 88.

Christen, Theodore Alphonse, Cincinnati; Universität Bern Medizinische Fakultät, Switzerland, 1894; served as French vice-consul for the Cincinnati area; died May 23, aged 91.

Codington, Herbert Augustus Ⓜ Wilmington, N. C.; University of Maryland School of Medicine, Baltimore, 1911; also a graduate in pharmacy; veteran of World War I; associated with the Community and James Walker Memorial hospitals; died May 21, aged 72.

Cohen, Manley Benjamin Ⓜ El Paso, Texas; Laval University Faculty of Medicine, Quebec, Que., Canada, 1942; interned at the Massachusetts Memorial Hospitals in Boston, where he served a residency; served a residency at the Charlotte Hungerford Hospital in Torrington, Conn.; fellow of the American College of Chest Physicians; member of the American Trudeau Society; veteran of World War II; chief of the medical staff at Providence Memorial Hospital, where he died May 24, aged 44.

Collins, Clarence Bythell, North East, Md.; University of Maryland School of Medicine, Baltimore, 1909; died in Elkton May 29, aged 75.

Cone, William Vernon, Montreal, Que., Canada; born in Conesville, Iowa, May 7, 1897; State University of Iowa College of Medicine, Iowa City, 1922; professor of neurosurgery at the McGill University Faculty of Medicine, where he joined the faculty in 1929; lecturer in neuropathology at his alma mater from 1922 to 1924; from 1926 to 1928 instructor of surgery at Columbia University College of Physicians and Surgeons in New York City; specialist certified by the American Board of Neurological Surgery; member of the American Association for the Study of Trauma, Canadian Medical Association, Harvey Cushing Society, American Neurological Association, American Academy of Neurology, and the Association for Research in Nervous and Mental Diseases; served overseas during World War II and helped organize the No. 1 Neurological Hospital, of which he was appointed chief neurosurgeon with the rank of lieutenant colonel; neurologist and neurosurgeon-in-chief, Royal Victoria Hospital; chief of neurosurgery service at the Montreal Neurological Institute, where he died in his office May 4, aged 61.

Craig, Frank Ardary Ⓜ Philadelphia; born in Philadelphia Sept. 28, 1876; University of Pennsylvania Department of Medicine, Philadelphia, 1898; emeritus professor of clinical medicine at his alma mater and emeritus professor of medicine at the University of Pennsylvania Graduate School of Medicine; veteran of World War I; member of the American Trudeau Society and the American Clinical and Climatological Association; a charter member of the National Tuberculosis Association; last December received the annual award of the Philadelphia Tuberculosis and Health Association "for a life time

---

Ⓜ Indicates Member of the American Medical Association.

of outstanding work in tuberculosis control"; first president of the Pennsylvania Trudeau Society and the William B. Lake Foundation; associated with the Phipps Institute of the University of Pennsylvania, where he served as clinical director; served as president and medical director of the White Haven (Pa.) Sanatorium; for many years a member of the visiting staff of the Philadelphia General Hospital, tuberculosis division, and a member of the executive committee of the medical board; consultant in tuberculosis at the Presbyterian Hospital and the Philadelphia General Hospital; author of "Diseases of Middle Life"; died in the Presbyterian Hospital May 11, aged 82.

Crowley, Daniel Francis Ⓜ Des Moines, Iowa; Creighton University School of Medicine, Omaha, 1906; associated with Iowa Lutheran Hospital, Iowa Methodist Hospital, and the Mercy Hospital, where he was once chief of staff, and where he died May 21, aged 81.

Cummings, Frank A. Ⓜ Providence, R. I.; Tufts College Medical School, Boston, 1912; on the courtesy staff of the Rhode Island Hospital, where he was on the active staff from 1919 to 1942; died May 6, aged 75.

Cunningham, Eric Alton Ⓜ Louisiana, Mo.; Washington University School of Medicine, St. Louis, 1926; served as president of the Pike County Medical Society; fellow of the American College of Surgeons; veteran of World War I; chief of staff, Pike County Hospital; member of the board of directors of the Bank of Louisiana; died May 6, aged 60.

Davis, Virgil Allen, New York City; University Medical College of Kansas City, Mo., 1910; died May 22, aged 78.

Dawson, Robert Lee, Bee Branch, Ark. (licensed in Arkansas in 1903); past-president of the Faulkner County Medical Society; died in Little Rock May 22, aged 79.

Dickey, James Lee, Taylor, Texas; Meharry Medical College, Nashville, Tenn., 1921; honored by the city of Taylor as its outstanding citizen of 1952; an engraved plaque given by four local civic clubs went to him; he was especially honored for the good work he had done toward eradicating typhoid fever, tuberculosis, and infant diarrhea among Negroes; died May 18, aged 65.

Dugdale, Allison Harold, Rutherford, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1913; died in New York City April 3, aged 71.

Dyer, Curtis William, Augusta, Maine; Medical School of Maine, Portland, 1918; member of the staff of the Augusta General Hospital; died May 19, aged 65.

Ellenberger, Joseph Mark Ⓜ Norristown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1912; died in the Montgomery Hospital May 5, aged 76.

Erskine, Gordon McClure Ⓜ Tucson, Ariz.; University of Minnesota Medical School, Minneapolis, 1938; practiced in Grand Rapids, Minn.; died in the Tucson Medical Center May 19, aged 59.

Fehland, Harold Roland Ⓜ Wausau, Wis.; University of Minnesota Medical School, Minneapolis, 1925; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; a vice-regent of the International College of Surgeons; served as chief of the surgical service, St. Mary's Hospital; died in Tomahawk May 6, aged 59.

Ferguson, Georgium Hill, Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890; died May 5, aged 92.

Fipphen, Earl Edward, Worcester, Mass.; Harvard Medical School, Boston, 1922; fellow of the American College of Surgeons; on the staff of the Worcester City Hospital, where he died May 10, aged 60.

Flynn, Eugene Ⓜ Pierre, S. D.; University of Arkansas School of Medicine, Little Rock, 1933; veteran of World War II; died in St. Mary's Hospital May 2, aged 54.

Fountain, John Horace Ⓜ Captain, U. S. Army, retired, Seattle; born in Washington, D. C., Feb. 16, 1905; Georgetown University School of Medicine, Washington, D. C., 1929; U. S. Army Medical School, 1931; director of the division of tuberculosis control, Seattle–King County Department of Public Health; director of the tuberculosis division, Colorado State Health Department, 1938-1939; served with the California State Department of Health; entered the regular Army in 1930 and retired Sept. 30, 1935; worked for the Washington State Health Department until 1944, when he was named superintendent and medical director of the Morningside Tuberculosis Hospital, remaining there until 1946; specialist certified by the American Board of Preventive Medicine; member of the American Trudeau Society and the American Public Health Association; clinical instructor in public health and preventive medicine, University of Washington School of Medicine; died May 1, aged 54.

French, Joel Erle, Memphis, Tenn.; Memphis (Tenn.) Hospital Medical College, 1908; on the staff of Baptist Memorial Hospital; died May 4, aged 81.

Fuerth, Arthur Laurence Ⓜ Cape Girardeau, Mo.; St. Louis University School of Medicine, 1916; fellow of the American College of Surgeons; veteran of World War I; at one time associated with the St. Louis City Hospital; associated with St. Francis Hospital, where he died May 2, aged 66.

Gittinger, William Carl Ⓜ Brooklyn; born in New York City June 24, 1926; New York Medical College, Flower and Fifth Avenue Hospitals, New York City, 1949; member of the New York Heart Association and the American Geriatrics Society; certified by the National Board of Medical Examiners; served as instructor in physiology, bacteriology, and medicine, assistant to the dean, New York Medical College, Flower and Fifth Avenue Hospitals, and instructor in medicine at the Yale University School of Medicine, in New Haven, Conn.; veteran of World War II; served as industrial medical officer at Boston Naval shipyard during the Korean War; medical director of Pfizer Laboratories division, Charles Pfizer & Company, Inc., New York City; died in Chase, Baltimore County, Md., May 12, aged 32.

Godbey, John Campbell Jr. Ⓜ Morenci, Ariz.; Southwestern Medical School of the University of Texas, Dallas, 1944; veteran of World War II; interned at Baylor University Hospital in Dallas, Texas, where he served a residency; formerly associated with the Johns Hospital in Taylor, Texas; on the staff of the Morenci Hospital; died May 7, aged 44.

Gosling, John Anthony Ⓜ Tiffin, Ohio; Rush Medical College, Chicago, 1901; veteran of World War I; for many years city health commissioner; surgeon for the New York Central Railway; on the staff of the Mercy Hospital, where he died May 8, aged 85.

Hampton, Henry Hunton Ⓜ Chattanooga, Tenn.; Johns Hopkins University School of Medicine, Baltimore, 1914; fellow of the American College of Surgeons; served as chief of staff at Mount Sinai Hospital in Baltimore; associated with Erlanger and T. C. Thompson Children's hospitals; a director of the Pioneer Bank; died May 8, aged 76.

Hartman, John Chilton, Campbellsburg, Ky.; University of Louisville Medical Department, 1908; died in the King's Daughters' Hospital, Shelbyville, May 4, aged 74.

High, Clifton Earle Ⓜ Pampa, Texas; Baylor University College of Medicine, Dallas, 1924; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; veteran of World War I; associated with the Highland General and Worley hospitals; died May 10, aged 59.

Hobbs, Armenious Clements Jr. Ⓜ Columbus, Ga.; born in Cataula, Ga., Jan. 27, 1920; University of Georgia School of Medicine, Augusta, 1946; served an internship at the Columbus City Hospital in Columbus, Ga., and a residency at Jefferson–Hillman Hospital in Birmingham, Ala.; specialist certified by the American Board of Ophthalmology; fellow of the American Academy of Ophthalmology and Otolaryngology; captain in the medical reserve corps of the U. S. Army, 1948-1949; on the staffs of St. Francis Hospital and Medical Center; consultant, Station Hospital in Fort Benning, Ga., and the Veterans Administration Hospital in Tuskegee, Ala.; served as secretary-treasurer of the Muscogee County Medical Society; an associate editor of the *Bulletin of the Muscogee County Medical Society;* president of the Columbus Philharmonic Guild; died May 8, aged 39.

Hockett, Lester Emlen Ⓜ Vancouver, Wash.; North Carolina Medical College, Charlotte, 1917; past-president of the Clark County Medical Society; received a citation and Congressional Medal of Merit for services rendered on the Selective Service Board during World War II and an award from the Governor for services on the Selective Service Board; past-president of the staffs of St. Joseph and Vancouver Memorial hospitals; chief surgeon of the Washington State School of the Deaf; died May 16, aged 68.

Hoy, Carl Da Costa, Columbus, Ohio; Northwestern University Medical School, Chicago, 1907; for many years associated with the White Cross Hospital; veteran of World War I; died May 5, aged 76.

Ireland, R. Lindsey Ⓜ Louisville, Ky.; Kentucky School of Medicine, Louisville, 1894; Louisville (Ky.) Medical College, 1894; for many years on the medical staffs of Norton Memorial Infirmary and Kentucky Baptist Hospital; staff physician for Southern Baptist Theological Seminary; chief of medical staff, Spring Meadows, Baptist orphanage at Middletown; died May 8, aged 86.

Jordan, George Thomas, Vermillion, S. D.; born in Vermillion, May 17, 1876; Rush Medical College, Chicago, 1905; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; professor of otolaryngology and ophthalmology at the University of South Dakota School of Medical Sciences and in 1957 was presented a distinguished service award at its annual banquet in recognition of his many years of service devoted to clinical instruction in the field of otolaryngology and ophthalmology; formerly practiced in Chicago, where he was on the faculty of Loyola University School of Medicine and on the staff of the Mercy Hospital; veteran of World War I; chief of staff at the Dakota Hospital; died May 17, aged 83.

Kilgore, Alson Raphael Ⓜ Belvedere, Calif.; born in Oakland, Calif., May 30, 1887; Harvard Medical School, Boston, 1914; member of the founders group of the American Board of Surgery; member of the American Surgical Association; fellow of the American College of Surgeons; past-president of the Pacific Coast Surgical Association, San Francisco Surgical Society, and the San Francisco Medical Society; veteran of World War I; served on the faculty of the University of California School of Medicine in San Francisco; until 1918 taught at the Harvard Medical School in Shanghai, China; first secretary-treasurer of the California Physicians' Service, of which he was a founder and an original trustee; chief surgeon for the Western Pacific Railroad for 25 years; associated with the Chinese Hospital; for many years chief of surgery at Children's Hospital and chief of staff at St. Joseph's Hospital in San Francisco, where he died May 20, aged 71.

Lee, Willard Judd, Garden City, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1923; served during World War I; veteran of World War II and was awarded a commendation citation; served on the staffs of the Nassau Hospital in Mineola, Mercy Hospital, Rockville Centre, and South Nassau Communities Hospital in Oceanside; formerly surgeon of the city fire department; died in the Memorial Hospital, New York City, May 11, aged 61.

Liepmann, Hans Walter Ⓜ Central Valley, N. Y.; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1925; school physician for the Monroe-Woodbury Central School District; on the staffs of the Goshen (N. Y.) Hospital, St. Luke's Hospital, Newburgh, and Cornwall (N. Y.) Hospital; died May 6, aged 56.

Linde, Herman Ⓜ Cyrus, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1905; died at the Stevens County Memorial Hospital in Morris May 10, aged 87.

McBain, Louis Bernard Ⓜ Appleton, Wis.; University of Wisconsin Medical School, Madison, 1930; veteran of World War II; member of the American Academy of General Practice; a member of St. Elizabeth's Hospital; died May 3, aged 53.

McKinney, Edgar Prentice Ⓜ Nacogdoches, Texas; University of Virginia Department of Medicine, Charlottesville, 1933; veteran of World War II; died in the Hermann Hospital, Houston, May 6, aged 51.

McKinney, Thomas Seldon Ⓜ born in Moonachie, N. J., Nov. 14, 1918; Maywood, N. J.; New York Medical College, Flower and Fifth Avenue Hospitals, New York City, 1944; certified by the National Board of Medical Examiners; specialist certified by the American Board of Anesthesiology; member of the American Society of Anesthesiologists; veteran of World War II; served in Korea in 1953-1954; assistant director of the department of anesthesiology at Hackensack (N. J.) Hospital, where he died May 4, aged 40.

McLeod, Donald Norman Ⓜ Tucson, Ariz.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1948; member of the American Academy of General Practice; associated with St. Mary's Hospital and the Tucson Medical Center, where he died May 5, aged 33.

Marks, Jacob Keene Ⓜ Philadelphia; Temple University School of Medicine, Philadelphia, 1914; veteran of World War I; for many years on the staff of the Stetson Hospital, where he died May 17, aged 66.

Meyer, Hugh Raymond Ⓜ Lansing, Mich.; University of Michigan Medical School, Ann Arbor, 1917; died May 5, aged 68.

Murphy, Harry E. Ⓜ Franklin, Ind.; born in Morgantown, Ind., Sept. 16, 1894; Indiana University School of Medicine, Indianapolis, 1918; past-president of the Johnson County Medical Society; member of the American Academy of General Practice; veteran of World War I; health officer of Johnson County; from 1945 to 1952 served as the Seventh District Republican chairman; on the staffs of Methodist Hospital, Indianapolis, and the Johnson County Memorial Hospital; died in St. Mary's Hospital, Rochester, Minn., May 8, aged 64.

Myers, John Llewellyn Ⓜ Des Moines, Wash.; born in Bedford, Mo., March 29, 1872; College of Physicians and Surgeons, Medical Department of the Kansas City University, Kansas City, Kan., 1904; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and for many years secretary of the section on otology, rhinology and laryngology; member of the American Laryngological Association and the American Association for the Advancement of Science; fellow of the American College of Surgeons; vice-chairman, Section on Laryngology, Otology and Rhinology of the American Medical Association, 1932-1933; in 1941 was presented a gold medal by the Kansas City (Mo.) Society of Ophthalmology and Otology, of which he was president in 1921, as a mark of appreciation of his work in the society; in 1931 president of the Kansas City Southwest Clinical Society; formerly on the staffs of the University of Kansas Medical Center, Kansas City, Kan., and Research and St. Mary's hospitals in Kansas City, Mo.; served as associate professor of otorhinolaryngology at the University of Kansas School of Medicine, Kansas City, Kan.; first president of the Alaska Board of Medical Examiners, of which he was an organizer; for many years practiced in

Ketchikan, Alaska, and served as a medical missionary; veteran of World War I; died May 20, aged 87.

Neraal, Paul O. ⓜ Cut Bank, Mont.; State University of Iowa College of Medicine, Iowa City, 1897; health officer of Glacier County from 1921 to 1956; served as county coroner and as physician for the Great Northern Railway; past-president of the North Central District Medical Association; associated with the Glacier County Memorial Hospital; died May 9, aged 88.

Northrop, David Daniel ⓜ Lansdale, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1931; veteran of World War II; regional medical director of Multiple Sclerosis Foundation; associated with Grand View Hospital in Sellersville and medical director of the North Penn Hospital, where he died May 24, aged 54.

Oates, Louis Thomas, Morrilton, Ark.; University of Arkansas School of Medicine, Little Rock, 1905; one of the organizers of the First State Bank of Morrilton, where he was vice-president and chairman of the board of directors; died May 2, aged 83.

Parker, Joseph B. ⓜ Knoxville, Tenn.; Tennessee Medical College, Knoxville, 1895; University of Louisville (Ky.) Medical Department, 1897; served as county physician for three years; elected to the office of register of deeds from 1932-1940; associated with the Fort Saunders Presbyterian Hospital; died May 13, aged 89.

Pensig, Arnold Walter ⓜ Brooklyn; born in Brooklyn Feb. 12, 1926; New York Medical College, Flower and Fifth Avenue Hospitals, New York City, 1948; interned at the Jewish Hospital in Brooklyn and the Bellevue Hospital in New York City; served a residency at the Goldwater Memorial Hospital in New York City and the Maimonides Hospital in Brooklyn; clinical assistant, medicine, State University of New York College of Medicine at New York City; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; member of the American Association for the Advancement of Science; a director of the Brooklyn Tuberculosis and Health Association; on the staffs at Maimonides and Kings County hospitals; associate medical director of Pfizer Laboratories division, Charles Pfizer & Company, Inc., New York City; served in the U. S. Public Health Service Reserve as medical officer at the U. S. Coast Guard Academy in New London, Conn., from 1956 to 1958; died near Baltimore May 13, aged 33.

Perkins, Joseph Ashbridge ⓜ West Chester, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1916; retired in 1957 as chief plant physician at Lukens Steel Company; on the staff of the Coatesville (Pa.) Hospital, where he died May 13, aged 67.

Postelle, Joseph McDowell ⓜ Houston, Texas; Baltimore Medical College, 1894; veteran of World War I; died May 14, aged 94.

Reagan, Rezin ⓜ Sioux Falls, S. D.; born in Sheridan, Ind., Nov. 8, 1882; Rush Medical College, Chicago, 1913; member of the American Academy of General Practice; past-president of the Seventh District Medical Society; served in France during World War I; formerly medical member of the claims rating board of the Veterans Administration regional office from 1954 to 1957; associated with McKennan and Sioux Valley hospitals; for many years medical director of the National Reserve Life Insurance Company; died May 10, aged 76.

Rowley, Robert Lee ⓜ Hartford, Conn.; Yale University School of Medicine, New Haven, 1903; retired in 1950 as medical director of the Phoenix Mutual Life Insurance Company; past-president of the Association of Life Insurance Medical Directors of America; for many years on the state medical examining board; associated with the Hartford Hospital, where he was a member of the board of directors from 1928 to 1958, and where he died May 5, aged 79.

Rund, Emmet Henry ⓜ St. Louis; National University of Arts and Sciences Medical Department, St. Louis, 1918; fellow of the American College of Surgeons; instructor in gynecology and obstetrics at St. Louis University School of Medicine; on the staff of St. Mary's Group of Hospitals, Alexian Brothers Hospital, Incarnate Word Hospital, Firmin Desloge Hospital, and St. Anthony's Hospital; associated with St. Louis City Hospital from 1930 to 1935; from 1933 to 1941 surgeon for the police department; died in St. Anthony Hospital May 19, aged 67.

Schatanoff, Louis ⓜ New Freedom, Pa.; Long Island College Hospital, Brooklyn, 1927; on the staff of the York Hospital; died May 7, aged 57.

Scheidell, Dorothy Katherine ⓜ Quincy, Mass.; Cornell University Medical College, New York City, 1932; fellow of the American College of Surgeons; associated with the Quincy City Hospital; on the staffs of the Faulkner and New England hospitals in Boston; died in the Massachusetts General Hospital in Boston May 5, aged 51.

Tupker, Eugene Powers ⓜ St. Helens, Ore.; Creighton University School of Medicine, Omaha, 1932; veteran of World War II; served on the staff of the Oregon State Hospital in Salem; died May 8, aged 52.

FOREIGN LETTERS

BRAZIL

Metaplasia of Gastric Mucosa.—According to Dr. Jorge Michalany (*Revista da Associação medica brasileira,* February, 1959) intestinal metaplasia represents the epithelial lesion of chronic gastritis and it may interfere with gastric secretion. The increased secretion of serotonin by argentaffin cells, which are increased in intestinal metaplasia, may cause hyperperistalsis. Intestinal metaplasia of the gastric mucosa is not necessarily precancerous, despite some reports to the contrary. The enteroid structure in most cases of gastric carcinoma depends, principally, on the metaplastic capacity of the neoplastic cells themselves.

Intervertebral Disks.—Dr. Rolando Tenuto analyzed a series of 128 patients operated on for herniated lumbar intervertebral disks. These patients had been carefully observed for at least one year (*Arquivos de neuro-psiquiatria São Paulo,* March, 1959). Good results, i. e., no remaining signs or symptoms, were obtained in 78.2%, improvement in 10.9%; and no relief in 10.9%. Operation is indicated in patients with this condition when (1) conservative treatment is ineffective, (2) sensory or motor deficits are evident, and (3) acute damage of several nerve roots is present. Myelography should always be added to the clinical examination, since it will localize the lesion.

GERMANY

Cerebral Tuberculomas.—Within seven years four cerebral tuberculomas were observed by W. Jacoby (*München. med. Wchnsch.* 101:890, 1959). In each case the diagnosis was made by histological examination of the resected lesion. In two patients the tuberculomas were found in the cerebral hemispheres, and in two others they were found in the posterior cranial fossa. Three patients recovered after operation and were cured. One patient died during the operation but would have died anyway because of the wide extent of the tuberculoma. Postoperative tuberculous meningitis, formerly a common and dreaded complication, can now be prevented by the use of streptomycin.

Anomalies in Newborn Infants After Estrogenic Treatment of Mothers.—Three cases of multiple gross developmental disorders were observed in newborn infants whose mothers had been treated with large doses of estrogens in the early stages of pregnancy. These were reported by H. Uhlig (*Geburtshilfe und Frauenheilkunde,* vol. 19, 1959). Estrogens had been given to two to induce abortion. The malformations involved the brain and spinal cord (hydrocephalus, meningomyelocele, and rachischisis), lungs, liver, spleen, intestine, muscles, and bones. Embryogenic considerations indicated that abnormal fetal development began synchronously with estrogen treatment. The assumption of a causal relationship between the latter and the observed developmental disorders was, therefore, justified. Experiments in pregnant rats, showing severe fetal damage after the administration of estrogens, support this view.

Carcinoma of the Ovaries.—The method used at the gynecologic clinic of the University of Heidelberg for the treatment of carcinoma of the ovaries was described in detail by Buttenberg and Lau (*Geburtsh. u. Frauenh.* 19:323, 1959). Treatment consists of (1) excision of both ovaries without removal of the uterus, or, if this proves impossible, removal of the bulk of the tumor masses, no attempt being made to radically eradicate all carcinomatous tissue; (2) repeated intra-abdominal instillation of 120 mc. of colloidal radioactive gold, the first being given immediately after the operation; (3) intrauterine application of radioactive cobalt (the maximum dose delivered to the bladder and rectum being 4,000 r), either deep x-ray therapy with one field each over the abdomen and the back with a surface dose of 6,000 r or telecobalt therapy with doses of 4,000 to 5,000 r is used; and (4) continuous therapy with large doses of androgens in combination with prednisone. With this treatment the survival time of 24 patients with incurable cancer of the ovaries could be prolonged by an average of three months, compared with a group of 29 similar patients treated during the period 1945-1950. In view of the unfavorable prognosis of carcinoma of the ovaries this prolongation of survival time, although small, is of some value, particularly as the patients regain a feeling of well-being. The use of cytostatic agents is rejected because of the additional risk of damage to the leukopoietic system, but hypophysectomy is advocated as a supplementary measure to hormone treatment.

Hyaline Membranes in Premature Infants.—Hyaline membranes are found primarily in premature infants and represent an exudation of blood con-

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

stituents in septums and alveoli of the lungs. Because of insufficient reabsorption these are condensed and cause a membranous strangulation of the peripheral respiratory passages. According to Braun and Mann (*Arch. Kinderh.* 159:130, 1959) these membranes may contain cellular materials, decomposition products, and lipid droplets. The blockade of the gas exchange converts the temporary anoxia of premature infants into a manifest anoxia and causes death. As with infants suffering from asphyxia neonatorum these infants have dyspnea, cyanosis, and occasionally attacks of apnea also. There is no effective treatment.

Neonatal Liver Function.—A series of liver function tests were performed during the first 10 days of life to evaluate the functional capacity of the liver in mature and immature newborn infants by Dieckhoff and Schmidt (*Arch. Kinderh.* 159:113, 1959). Particular attention was given to the intravenous levulose tolerance test. This test, when showing pathological values, confirmed the results of the serum bilirubin determination, the sulfobromophthalein test, and the electrophoretic pattern of the serum during the same period of life. The reduced capacity of the liver of the newborn, interpreted as functional immaturity, was shown by the following results, premature babies showing weaker function than full-term infants.

In premature infants serum bilirubin concentration was at all times higher than in full-term infants. Most of the total bilirubin consisted of indirect-reacting bilirubin. In 35% of the infants examined the presence of direct-reacting bilirubin could be shown. The retention of sulfobromophthalein in the blood decreased with increased age but did not depend on the birth weight. When correlated with the simultaneous bilirubin level there appeared to be a coexisting disturbance of two partial functions. In premature infants serum electrophoresis revealed an increase of the albumin fraction with lowered values for the globulins, and hypoproteinemia was more marked than in full-term infants. When comparing full-term and premature babies with older infants there was a definite reduction in the breakdown of levulose after intravenous loading. Particularly 20 to 60 minutes after injections the levulose concentration in the blood of immature newborn infants was above normal.

Antibiotic-Resistant Staphylococci.—L. Grün of Düsseldorf (*Die Medizinische*, no. 4, p. 143, 1959) stated that in addition to the problem of the development of antibiotic-resistant (AR) staphylococcic strains in hospitals there is the problem of the transmission of AR to the general public by healthy carriers. Some of these strains may cause small epidemics. Staphylococcic respiratory diseases are clearly on the increase. In many cases an infection with an AR strain becomes manifest only after discharge from hospital. The importance of pathogen-carrying hospital personnel who contribute to the spread of epidemic strains is recognized. Whether infection is transmitted through the air or by contact has not been determined, but it appears likely that both these modes are operative. Ultraviolet irradiation of the air in the operating room greatly reduces bacterial contamination. Another helpful measure is an increase in the air circulation. Although the elimination of all carriers of the infection is not possible the rate of infection can be lowered by ultraviolet irradiation, spraying with triethylene glycol, and disinfection of linen. Beds should be made of latex foam, which is bactericidal in itself.

Streptococcic Infections.—W. Schmid of Würzburg (*Med. klin.* 54:296, 1959) studied serums from 60 patients for antistreptolysin and C-reactive protein levels. In 16 patients (4 who had rheumatic polyarthritis with cardiac involvement, 9 who had endocarditis with acute rheumatic polyarthritis, and 3 who had septic fever of unknown origin) the two reactions were parallel. In the others (those with acute nephritis, rheumatoid arthritis, and rheumatic manifestations without cardiac involvement) only the antistreptolysin values were elevated. It was concluded that the antistreptolysin levels were a more reliable criterion of the activity of inflammatory rheumatic diseases than the demonstration of C-reactive protein, although the latter also tends to decline in response to adrenocortical hormone therapy. The principal difference was that antistreptolysin develops only after immunization with streptolysin O, which is produced by beta hemolytic streptococci, while C-reactive protein may occur in diseases of various origins.

Circumscribed Opacities in the Lung.—F. Lindner of Berlin (*München. med. Wchnschr.* 101:787, 1959) studied a series of circumscribed opacities in the lung and found that 31.9% were carcinoma, metastases, or sarcoma; 14.6% were benign tumors (hamartoma, chondroma, bronchial adenoma, mesothelioma, neurofibroma, or hemangioma); and 53.5% were caused by inflammatory changes (tuberculosis, chronic pneumonic foci, cysts, pulmonary abscesses, pneumomycoses, or parasites such as Echinococcus). In most cases a clearcut diagnosis could be obtained only by thoracotomy. Differential diagnosis by radiology was inconclusive, even when it gave some indications of form, localization, and structure. Rapid growth indicated sarcoma. In advanced age carcinoma might also be suspected. All diagnostic aids should be used in the diagnosis of circumscribed tumors. Since the operative death rate associated with the removal of circumscribed tumors is low, surgical removal should always be resorted to.

Postoperative Hepatic and Renal Complications.—H. E. Bock of Marburg (*München. med. Wchnschr.* 101:785, 1959) stated that hepatic complications (19 of these hepatorenal) occurred after 119 of 6,000 major operations and caused 60 deaths. Postoperative renal damage was much more frequent. Operation in the presence of renal damage is associated with a major risk. Of 139 patients with an elevated nonprotein nitrogen level who were operated on 70 died. Nonprotein nitrogen and creatinine level determinations should always be made prior to operation. The urea clearance test is recommended only if the creatinine level exceeds 1 mg.%. If hepatic damage is suspected, the author recommended withdrawal of proteins, anticoagulants, mixed infusions (levulose, electrolytes, and metabolites), and prednisolone, and avoidance of the use of the duodenal tube for aspiration and feeding. To bridge the prolonged stage of anuria, hemodialysis is the only effective treatment. No disease should be judged from the laboratory findings alone, however important they may be, but all clinical findings should be considered.

Postoperative Infusions of Electrolytes.—H. Herken of Berlin (*München. med. Wchnschr.* 101:785, 1959) stated that in health the delicate electrolyte regulatory system keeps the water and salt content constant within a comparatively narrow range. The antidiuretic pituitary hormone and certain corticosteroids (especially aldosterone from the adrenals) have a major share in these regulatory processes. Because of postoperative changes in the production of adrenocortical hormone marked retention of sodium and an increase of the excretion of potassium occur. If secretion of urine is restricted, extrarenal losses of fluid (insensible perspiration) lead to the accumulation of sodium chloride. The postoperative regulatory disturbance is reversible. Infusions of electrolyte solutions are merely intended to compensate for postoperative fluid losses and to maintain diuresis. If the daily amount of urine is 600 cc., and the water loss with the stool about 200 cc., the quantity lost by perspiration is to be calculated as 1,000 cc. Thus, it is necessary to replenish 1,800 cc. of fluid. To prevent the retention of substances likely to be excreted with the urine a daily minimum of 500 to 600 cc. of urine is required. Morphine, hexobarbital, and chlorpromazine impair diuresis. Since hormones are unsuccessful in preventing electrolyte disturbances, the clinician should wait for spontaneous remissions.

Parenteral Feeding.—O. Lindenschmidt of Hamburg (*München. med. Wchnschr.* 101:786, 1959) stressed the importance of parenteral nutrition in the postoperative period until fluids can be taken by mouth. Entirely parenteral feeding should not be extended any longer than necessary and never beyond three or four days after the operation. If necessary tube feeding may be used. To prevent postoperative disorders it is necessary to compensate for any preoperative deficit in proteins. Careful preparation for operation is more important, more reliable, and less complicated than postoperative substitution by infusions. Preoperative protein loss can best be compensated by administration of whole blood or plasma and human albumin. Preoperative administration of amino acid mixtures is not very suitable; 30% is excreted and of the other 70% most is decomposed, so that little remans available for the synthesis of albumin. Plasma and human albumin do not need calories to be split. Postoperative energy supply is best provided by dextrose or levulose infusions. The administration of 200 to 250 cc. of whole blood, plasma, or human albumin is also recommended. Only in the late phase, when special importance is attached to protein-rich nutrition, is the administration of amino acid mixtures a suitable supplement. Indiscriminate infusion is dangerous. Clinical observations (thirst, moisture of skin and mucosa, nausea, and dizziness) should always be considered, apart from laboratory findings. Also, an excess of infusions and transfusions is dangerous.

Tuberculous Osteitis.—K. Treppinger (*Ztschr. Tuberk.-Arzt.* 13:106, 1959) reported on a series of 213 patients with tuberculous osteitis who received, in addition to the usual treatment, 3 to 5 mg. of isoniazid per kilogram of body weight. He concluded that therapy with isoniazid does not directly shorten the course of the disease, but it quickly brings the patient to a stage in which he can be operated on. The prospects for lasting ability to work were greater in these patients the longer the period of isoniazid administration had been. The incidence of relapses and flare-ups of new foci also diminished proportionately with the length of this treatment.

Isoniazid Therapy.—G. Bahrs (*Ztschr. Tuberk.-Arzt.* 13:157, 1959) made follow-up examinations of 200 patients who had received 10 mg of isoniazid per kilogram of body weight daily. About 33% of the patients had been pretreated with vitamin D or amithiozone. Of 159 patients with skin tuberculosis so treated 114 or 71% and of 119 patients with lupus vulgaris 76 or 64% remained cured. With a total dosage of 120 to 200 Gm. of isoniazid only three patients were not primarily cured. Of 24 patients with tuberculosis cutis indurativa cure persisted in 14 and failed in 6. Patients with mucosal lupus erythematosus responded well to isoniazid as did those with tuberculosis cutis verrucosa. There was no failure and no relapse in six patients treated with 40 to 60 Gm. of isoniazid. Patients with tuberculosis of the lymph nodes and tuberculosis cutis colliquativa responded less well and those with papulonecrotic tuberculides poorly. Long-term treatment with isoniazid alone, which is successful in dermal tuberculosis, is now rarely used in pulmonary tuberculosis. Therefore, it is not yet possible to evaluate this form of treatment in pulmonary tuberculosis. While para-aminosalicylic acid has completely failed in dermal tuberculosis, streptomycin is effective.

INDIA

Concentration Methods for Intestinal Parasites.—P. T. Acharya and co-workers (*Journal of the Indian Medical Association*, vol. 32, April 16, 1959) compared four methods of detecting protozoal cysts and helminthic ova in 400 samples of feces. The methods used were (1) direct examination of a wet preparation, (2) acid-ether concentration, (3) zinc sulfate concentration, and (4) brine flotation. Direct examination of a wet preparation was superior to the acid-ether method, except for the detection of cysts of Entameba coli. In the latter method the cysts became distorted and unrecognizable. The zinc sulfate method was superior to both the above techniques. The brine flotation method gave disappointing results, especially for the detection of Giardia lamblia cysts. Cysts were detected in 18 samples by direct examination when they were missed by all the other techniques. This method should therefore always be used with the zinc sulfate concentration technique. The acid-ether method was more useful than direct examination for detecting hookworm ova. For detecting ova of Ascaris lumbricoides, Trichuris trichiura, and Enterobius vermicularis, the acid-ether method did not give better results, and for ova of Hymenolepis nana direct examination gave much better results. The zinc sulfate method proved much more useful than both these methods for helminthic ova also. The brine flotation technique was even better, the best results being obtained by brine flotation along with the direct examination. Thus for protozoal cysts the zinc sulfate concentration method was most efficient, and for helminthic ova the brine flotation technique gave the best results.

JAPAN

Narcotics Problem.—The Bureau of Health and Welfare reported that crime waves related to narcotics addiction are on the increase. The number of arrests for violations of narcotics laws in 1952 was 982 and in 1958 was 1,767. As in the United States unwise narcotics laws have forced addicts to become peddlers of drugs from illegal sources. About 25% of the offenders are women. The government abolished legalized prostitution, but, since no funds were provided for the rehabilitation of these girls, many have turned to peddling narcotics. Of those arrested 68% were themselves addicts.

NORWAY

Alkaline Phosphatase and Iron in Jaundice.—J. S. Bødtker (*J. Oslo City Hosp.* 9:62-71 [March] 1959) studied the serum alkaline phosphatase and serum iron levels to determine their value in the differential diagnosis of jaundice. His series of 128 patients consisted of all patients over 20 years of age admitted between 1953 and 1957 to the Aker Hospital with a diagnosis of acute or chronic hepatitis, cirrhosis of the liver, stone in the common bile duct, cancer of the liver, cancer of the gallbladder, cancer of the pancreas, or jaundice; 12 patients with cholecystitis and cholelithiasis were included for the purpose of comparison with the group that had cholelithiasis alone. Increased values were found in all those with extrahepatic or intrahepatic obstructive jaundice. Alkaline phosphatase levels provided no clue to a differentiation between extrahepatic obstructive jaundice and primary intrahepatic cholestasis. Moderately increased phosphatase values were generally encountered during the initial phase in those with acute hepatitis but occasionally also in other groups with more complicated findings, probably indicating a phase of intrahepatic cholestasis.

A correlation between serum alkaline phosphatase and iron levels and icterus index could not be demonstrated. Acute hepatitis in early stages was associated with an increase in serum iron level in about 75% of the patients. In those with cirrhosis of the liver and chronic hepatitis high normal values were usually encountered, while low normal values were noted in those with obstructive jaundice due to calculi or malignant tumor, and in those with cholecystitis and cholelithiasis. Patients with drug-induced intrahepatic cholestasis had normal values. Serum iron estimations might be useful in the differentiation between intrahepatic and extrahepatic cholestasis.

SWEDEN

Precancerosis of the Penis.—Edsmyr and Ekström (*Acta chir. scandinav.* 116:296-305, 1958/1959) described precancerosis of the penis as an exophytic papillomatous lesion of the glans and prepuce which in histological examination shows no definite infiltrative growth. Compared with penile cancer it is fairly uncommon. The present series comprised 25 patients, of whom 15 had phimosis. Nine had had the condition since childhood and the other 6 had had surgical treatment for phimosis 5 to 30 years before the precancerous lesions were observed. The age distribution was similar to that in patients with cancer of the penis, but the mean age was somewhat lower. Phimosis seemed to have the same etiological significance as in cancer of the penis. Venereal disease was not an important factor in causing precancerosis, nor is it in patients with cancer. The macroscopic appearance of precancerosis does not usually differ from that of the papillary form of penile cancer, although the local extent of precancerosis is often greater.

Biopsy specimens from penile tumors seemed almost always to permit reliable histological diagnosis and to be representative of the tumor in question. In none of the authors' series did precancerosis of the penis give rise to inguinal metastases or undergo changes to infiltrative cancer. A trial of conservative therapy, reserving amputation for unsatisfactory results, would thus seem to imply no risk. Because the series was small the authors believed that it allowed no reliable comparative evaluation of different types of conservative treatment. Radiotherapy probably was the most effective and most suitable measure and appeared to be preferable to electrocoagulation. Only if precancerosis was confined to the prepuce was local excision (circumcision) justified. Of 18 conservatively treated patients 4 later underwent amputation. In three the indication was recurrence of the growth and in the fourth amputation was performed for irradiation necrosis 10 years after radiotherapy was begun. The other 14 patients showed no recurrence. Ten of them were followed up for 4 to 14 years and four for shorter periods. The results of conservative therapy were also good from the functional aspect. In no case did the treatment cause impotence. Twelve of the patients received prophylactic treatment consisting of telegamma rays in fractionated dosage, totaling 3,000 to 4,500 r to each of two fields in either groin (the same dosage as in cancer of the penis), and the other 13 patients had no inguinal irradiation. The authors concluded that irradiation of the inguinal lymph nodes in precancerosis is superfluous.

Scandinavian Hospital in Seoul.—Up to March 31 the Scandinavian teaching hospital in Seoul, Korea (opened in November, 1958), had treated 878 inpatients, and the outpatient department had had 7,100 visits from 3,801 registered patients. There are 90 Scandinavians on the hospital staff. Qualified assistant Korean staff members are still hard to find.

Artificial Nose.—An artificial nose was designed by Prof. Hjalmar Koch and co-workers. The apparatus, which takes over the function of the nose by giving the inhaled air body temperature and saturating it with moisture, is of great value to patients on whom it has been necessary to perform a tracheotomy. Formerly, tracheotomy was performed mainly as a lifesaving operation in patients with inflammation of the trachea, false croup, and true croup, but the circumstances changed radically during the severe poliomyelitis epidemics in the 1940's and 1950's. At the meeting of the Swedish Otolaryngological Society in Lund in May Prof. Koch stated that poliomyelitis also caused paralysis of the muscles of the pharynx and trachea. These patients lost the power to get rid of the secretions which run from nose and throat into the lungs and thus they drown in their own secretions. The respirator does not adequately serve its purpose, since the prime necessity is to keep the air passages free from obstruction. The artificial nose has helped to solve this problem.

UNITED KINGDOM

Penicillin-Resistant Staphylococci.—The rising incidence of penicillin-resistant strains of Staphylococcus aureus in hospitals is due to a real increase in penicillin resistance and to cross-infection in the wards. Little information, however, is available on the incidence of resistant strains in the general population. To obtain an indication of this Buhr and Scott studied strains isolated from hospital outpatients with hand infections (*Lancet* 1:1019, 1959). These were chosen because in the same unit six years ago these workers noted that of 82 hand infections due to Staph. aureus no penicillin-resistant strain was found. Swabs were taken from 290 patients treated in the accident service of the united Oxford hospitals. Of these 267 patients were from the general public and 23 were doctors, nurses, hospital personnel, or hospital staphylococcus contacts. Of the swabs from infected lesions of these 23, penicillin-resistant staphylococci were found in 16 (68%) in contrast to 30% of those from lesions in patients from the population at large. Of the penicillin-resistant organisms in the hospital staff 6 or 29% were also resistant to chlortetracycline. In nurses the percentage of penicillin-resistant strains of staphylococci reached 97%. Of 187 outpatients from the general population who had not had penicillin therapy for the hand infection under review 27% had penicillin-resistant strains of Staph. aureus, compared with 37% of those who had received penicillin some time previously.

The data confirm not only the high incidence of penicillin resistance among hospital staff, particularly nurses, but also among the general population, which has increased from 0 to 30% in the Oxford area within six years. The authors pointed out that, with hospital staphylococci so often resistant to penicillin, all available methods should be used to reduce hospital infection. The introduction of antibiotics has increased, not decreased, the need for aseptic and antiseptic vigilance.

The Church and Medicine.—Writing in the *Canterbury Diocesan Notes* the Archbishop of Canterbury said that there has always been a natural and inevitable affinity between the church and the medical profession, since their ministries of healing cannot be separated, but it had come to appear to many people that in their partnership the one was scientific and authoritative and the other sentimental and subsidiary. There is in many quarters a renewed sympathy between the two and a recognition that in many ways neither can do the perfect work of healing without the cooperation of the other. On neither side of the partnership is there infallibility. Neither can dictate to the other, but in their joint pursuit of spiritual and physical health they need each other. This is especially so when they deal from either side with questions that are moral as much as or more than medical. A physician is perfectly free to publish an article disagreeing with the church's view of fornication or other moral aberrations, but great injury to both sides of the partnership results, unless he makes it clear that he does not speak for his profession and that the fact of his being a doctor does not give him any special competence to deliver judgment on moral questions. It is always a serious matter to take the law, moral or civil, into one's own hands.

Effect of New Steroid on Synovial Fluid.—Few studies have been made of the biochemical and cytological changes occurring in synovial fluid after the intra-articular injection of steroids. Murdoch and Will (*Brit. M. J.* 1:1271, 1959) injected a new steroid, prednisolone trimethylacetate, into joint spaces. This drug is said to have a lower solubility than hydrocortisone and to remain in the synovial fluid longer. A clinical appraisal was first made of the effect of giving this new steroid intra-articularly to 35 patients with rheumatoid arthritis, osteoarthritis, and recurrent hydrarthrosis; 20 mg. of a microcrystalline suspension was injected into the knee joint. The effectiveness of treatment was measured by reduction in size of the swollen joint and by relief of pain. From 2 to 12 injections were given at intervals of one week. In the group with rheumatoid arthritis the results were good in 85.0%, fair in 7.5%, and poor in 7.5%. Only six patients with osteoarthritis were treated and the results were good in only two. In two patients with hydrarthrosis the results of treatment were good. A study of the patients over a 14-month period showed that prednisolone trimethylacetate was an effective agent for the intra-articular treatment of inflammation of the knee joint and compared favorably with hydrocortisone used for this purpose.

Before each injection a small amount, usually 3 to 5 ml., of joint fluid was removed for analysis. Viscosity and protein and mucin content were determined, and total and differential leukocyte counts were made. Electrophoresis of the fluid was carried out. The percentage distributions of the various protein fractions were calculated, and from the total protein figure their absolute values were obtained. Marked changes occurred in the cell count of the synovial fluid of patients with rheumatoid arthritis treated with prednisolone trimethylacetate. The initial average cell count was 7,000 per cubic millimeter. The initial proportion of polymorphonuclear cells (75%) dropped by 85% after treatment. The protein level fell from an average of 4.4 to 3.4 Gm. per 100 ml. Most of the patients showed a rise in albumin content and a fall in the alpha, beta, and gamma globulin fractions. There was a progressive reduction in the volume of the joint fluid and an increase in viscosity.

The group of osteoarthritic patients was too small for detailed analysis. The cell changes were similar to those occurring in patients with rheumatoid arthritis. The protein content of joint fluid was lower (3.3 Gm.) and it fell to 2.3 Gm. per 100 ml. after treatment. The albumin content was higher than in the rheumatoid arthritic patients. In the two patients with hydrarthrosis the cell count fell from 14,000 and 40,000, respectively, to 400 and 800 per cubic millimeter. The total protein level dropped from 4.35 to 3.3 Gm. per 100 ml. In other respects the findings resembled those in the patients with rheumatoid arthritis. In all patients the clinical improvement was directly associated with the cell and protein changes described.

Cor Triatriatum.—In cor triatriatum, only 20 cases of which have been described, the left atrium is divided by a septum into two chambers, a posterosuperior which receives the pulmonary veins and an anteroinferior which opens into the mitral valve and left ventricle. Since the septum causes an obstruction at left atrial level, the symptoms, radiologic appearances, and hemodynamics of mitral stenosis may be simulated. The condition is eminently suitable for surgical treatment, yet only three successful cases had been reported until Belcher and Somerville added a fourth (*Brit. M. J.* 1:1281, 1959).

A woman, aged 28, was suspected of having mitral stenosis. She was dyspneic, tired, and suffering from palpitations. The main auscultatory findings were a mitral pansystolic murmur (grade 2) and a loud first sound in the mitral (grade 3) and tricuspid (grade 3) areas. The ECG showed atrial fibrillation and right ventricular hypertrophy. The heart, especially the left atrium, was enlarged and the pulmonary artery was prominent. Cardiac catheterization was unsuccessful. The patient was operated on with a view to correcting the supposed stenosis, when the intra-atrial septum was found. It contained a calcified orifice on the posterolateral aspect. The septum was divided from side to side of the atrium. Immediately the pressures in the pulmonary artery and left atrium fell. Four months later the patient had no symptoms. The venous pressure was now normal, but atrial fibrillation and the mitral systolic murmur persisted. In the four patients with this rare condition who were operated on the diagnosis was only made after exploratory cardiotomy.

The Death of General Practice.—In an article entitled "The Decapitation of General Practice" (*Lancet*, May 16, 1959, p. 1039), Dr. E. Geiringer analyzed what he considered one of the major flaws of the National Health Service (NHS), namely, the payment of general practitioners by capitation fee. Under this system a practitioner undertakes to provide medical care for a fixed annual fee for each patient on his list. If this fee were large and all doctors equally competent and conscientious such a system would provide an ideal medical service, but when this fee is economic for the state and uneconomic for the doctors, who are a heterogeneous group with variable skills and no overwhelming desire to sacrifice themselves, payment by capitation fee encourages them to do less and less for more and more patients. Three results of the nationalization of medicine, the author said, are bad practice, the utility-type practitioner, and the hospitalization of medical practice.

The bad practice falls below all reasonable professional standards. It is conducted from antiquated and badly maintained offices, examinations are perfunctory, equipment is outmoded, no proper records are kept, and treatment consists of the indiscriminate renewal of prescriptions for a dozen or so standard drugs and mixtures. Such practices are still common in industrial areas. Under the per capita system of payment this type of pauper medicine is profitable. A fee-for-service system would eliminate such practices in a few years.

The utility practitioner, on the other hand, is competent, honest, and hard-working. Having accepted the realities of the NHS he tries to make the best of it by having as many patients as possible on his list and giving each a just proportion of his time. The time spent per patient equals the number of hours available divided by the number of patients requiring treatment. By making the latter maximal the time spent on each is minimal. Simple medical care is conscientiously prescribed, but this is the limit of treatment. A patient needing further investigation is referred to a hospital. The numerous psychoneurotic patients are a great worry to the utility practitioner, because he has no time to listen to them. He is not happy to have on his list people who are ill, although he accepts them from a sense of duty. His favorite patients are those who never have any need of his services. Pregnant women go to the nearest antenatal clinic and babies to the infant welfare clinic. Minor surgery is referred to the casualty department of the nearest hospital. Slowly but surely he loses his skill, knowledge, and interest in medicine.

As hospitals expand to do the work of the general practitioner, with special departments and staff for this purpose, a vested interest is created. The public now expects all treatment beyond the most simple to be given in hospital. Every year there are 11,500,000 attendances at hospital casualty departments for minor injuries that could be treated by general practitioners but are treated by relatively inexperienced interns. Litigation favors this. If anything goes wrong the general practitioner is blamed in the courts for not sending the patient to hospital. These considerations apply to a number of other activities that general practitioners have tended to hand over to hospitals and clinics. They include antenatal and postnatal care, deliveries, the care of mother and child, child health, acute infections that could be treated at home, the care of the moribund, and minor psychotherapy. This progressive hospitalization of medical care threatens to abolish general practice in all but name. It is encouraged by medical research, which draws the patient from the home into the hospital for investigation. Hypertension, diabetes, pneumonia, coronary disease, and rheumatism, to mention only a few, have become vested hospital interests. If general practitioners are paid for what they do and not for what they do not do there will be a tendency for them to use modern medical techniques and keep up to date, because then the best practitioners will attract the most patients. There is no reason why general practitioners should not do their own diagnostic radiography and electrocardiography; supervise anticoagulant and steroid therapy; stabilize hypertensive, diabetic, and epileptic patients; and treat patients with pneumonia, acute infections, and coronary disease in the home or in the local hospital. They could cooperate with hospital specialists in treating such patients.

Under the capitation system the introduction of new methods, techniques and investigations into general practice results in pecuniary loss to the doctor because it has to be financed by him. Every day general practice loses something to the hospitals and in return gains nothing. Great Britain now has the most restricted and out-of-date form of general practice of any English-speaking country. The general practitioner has become merely a signer of certificates and a hospital signpost, the author claimed. The existence of a good general practitioner service is essential to inspire the patient's confidence, to insure his continuity of treatment when hospitalized, and to maintain a good consultant service. Healthy and independent general practice exerts a constant pressure on the hospitals and consultants, keeping them efficient and humane. By taking a personal interest in their patients, following their course in hospital, conferring on the spot with hospital colleagues, and having freedom to choose a consultant, general practitioners can prevent complacency, inefficiency, and inhumane treatment in the hospitals. Under the present system consultants can also stagnate professionally because there is no outside pressure from general practitioners to keep them on their toes and be their rivals.

The author made a plea for the resurgence of private medical practice, which would exert a healthy influence on the hospital service and safeguard professional freedom. A salaried service is not the answer; although it would abolish "head-hunting," it would not allow patients freedom to choose their doctors. A bad doctor would still be paid as much as a good doctor. A fee-for-service system would rehabilitate the present moribund service by the working of economic laws. As it is more economic to treat patients in general practice than in hospitals, funds could be diverted from them to an enlarged, better paid, and more efficient general practitioner service. Overtreatment is one of the objections to a fee-for-service system, but this could be checked by making the patient pay a part of each fee charged. Other measures to encourage general practice would be increased facilities and financial incentive for home treatment and general practitioner appointments in local hospitals, which should include inpatient care and supervision.

Cataract Extraction with Alpha Chymotrypsin.—Alpha chymotrypsin (ACT) is an enzyme with fibrinolytic and proteolytic properties, obtained from bovine pancreas. It has a selective solvent action on the zonule supporting the crystalline lens, and when introduced into the anterior chamber of the eye after corneal section it causes complete lysis of the zonule in about three minutes at body temperature. The extraction of 180 cataracts with the aid of ACT was described by Cogan and coworkers (*Brit. J. Ophth.* 43:193, 1959), Ainslee (*ibid.*, p. 200), and Zorab (*ibid.*, p. 202). The ACT was used at a concentration of 1:5,000. Since the solution is relatively unstable at room temperature it was either freshly prepared or stored in a refrigerator until required. Local anesthesia was used for most patients, after premedication with chlorpromazine and pentobarbital. A Von Graefe section was made, followed by peripheral iridectomy, and after irrigating the anterior chamber with Ringer's solution to remove clotted blood the ACT solution was injected through the iridectomy opening. After three minutes the anterior chamber was irrigated to remove the ACT and the lens removed by traction with forceps or by suction. It was removed easily, since there was no suspensory ligament holding it back. The removal of senile and presenile cataracts is made much easier by the use of ACT, which does not damage any of the ocular structures. No serious complications occurred during the operations.

Atomic Fall-out Hazards.—Mr. Macmillan, the Prime Minister, in a statement before Parliament, said that even if the deposition of radioactive strontium (Sr^{90}) that has already been released into the stratosphere from nuclear explosions continues at the higher rate recently observed, its concentration in bone is unlikely to approach the level which would require immediate action. For several years measurements of the deposition of Sr^{90} and other radioactive isotopes have been made. Recent measurements indicate that the rate of deposition in rainfall is double that of a few years ago. Analysis of fall-out material shows that Sr^{90} can remain in the stratosphere for many years before being deposited on the earth. The annual fall-out is about 12% of the stratospheric content. Once radioactive materials have left the stratosphere and entered the troposphere the local rate of deposition depends largely on rainfall. Heavy rainfall increases fall-out, and this was one of the factors responsible for the high fall-out in 1958. The atomic bomb tests conducted in the U. S. S. R. last year were also contributory. The Argus experiments made at the same time in the United States resulted in only a small addition to the radioactivity of the stratosphere.

In Britain regular measurements are made of Sr^{90} in food, milk, drinking water, air, soil, and vegetation. Samples are regularly collected from 200 depots handling 40% of the milk consumed in the country. Cereals and vegetables, both home grown and imported, are also tested. The results of the 1958 food survey are now being prepared for publication. They indicate that the amount of Sr^{90} in food and drinking water gives no cause for alarm. Most of that present in milk is due to the isotope that has been freshly deposited on grass before it has a chance to be washed into the soil. If the enhanced fall-out of 1958 were to continue in 1959 an increase in the Sr^{90} of the diet could be expected, but Mr. Macmillan assured Parliament that its concentration in human bone was not a cause for anxiety. The Sr^{90} concentration found in 1958 in the bones of stillborn children and in those dying from various causes was only slightly above that of the previous year. The irradiation of human bone and marrow from Sr^{90} is less than that due to the natural background irradiation to which all are exposed.

Mr. Macmillan stated that cesium-137 is not readily taken up from the soil by plants and is not retained in the body for long periods. The chief danger is a genetic one, although gonadal exposure is small in relation to natural background irradiation. The absorption of plutonium from fall-out is low in comparison with that of Sr^{90}. Carbon-14 has been measured in air and foods for many years. Most of it comes from cosmic radiation, but a small amount also comes from atomic explosions. Its concentration is being kept under review because of its long persistence.

Qualified but Unable to Practice Medicine.—Nationals of British colonies who wish to practice medicine in their own countries after qualifying abroad often find it difficult to do so. The law prevents their practicing unless they have a qualification which is recognized in the colony, which usually means one that is registerable in Great Britain. In the last year 300 students from British colonies were working in medical schools in Canada and the United States, and about 450 were pursuing premedical studies, but as Great Britain has no reciprocal arrangement with the United States, nor with 4 of the 10 Canadian provinces, medical qualifications obtained in any of the approved American or in 8 of the 12 Canadian schools are not recognized in British colonies. Hence, most of these students will be legally prevented from practicing in their homeland, however good the status of their medical school or excellent their record. They must first seek additional qualifications from Great Britain or from a country that has established reciprocity with Great Britain.

Doctors from most islands in the West Indies, Trinidad, the Leeward Islands, Hong Kong, North Borneo, Kenya, Rhodesia, Uganda, and Fiji are required to hold a qualification registerable in Great Britain. Those from the Bahamas, Bermuda, British Honduras, Cyprus, Singapore, and Tanganyika who qualify outside Britain may be permitted to practice in some precarious form of temporary and localized licensure, or by legal subterfuge. Others are more fortunate. Thus, physicians from the Tonga Islands can be registered if trained in American schools. In Jamaica physicians may take the examinations without retraining, but in the Barbados registration is curiously confined to those entitled to practice in New York state, and in British Guiana it is open to those with a degree from a medical school approved by the American Medical Association. Nigeria has recently opened its doors to those persons holding the diploma of the National Board of Medical Examiners in the United States. In spite of the high academic standing of the medical schools of McGill or Toronto universities in Canada, qualifications obtained there are not acceptable, because these schools do not maintain reciprocity with the General Medical Council of Great Britain.

The avenue of the American-trained student is usually through one of the Canadian schools having reciprocity with Great Britain, but this requires time and money after the qualifying examination. As a result of these restrictions many British colonials are settling in the countries in which they were trained, while their own countries remain desperately short of doctors. There is still only one physician to every 50,000 persons in Nigeria. It has been suggested that wherever the colonial medical student may have studied he should be able to take a local registration examination preceded by a local internship. This could be controlled by a Commonwealth Board of Medical Examiners, which would be charged primarily with exploring the prospects of extended intern posts for approval and assisting in the local examinations.

Tranquilizer Hazards.—A report on hypnotic, sedative, tranquilizing, or stimulating drugs that can be bought at drug stores without prescription was sent to the Minister of Health by the recently formed Advertising Inquiry Committee. The medical panel of the committee drew up the report after a survey of advertisements in the press and on television. There is a British Code of Standards on the advertising of medicines and surgical appliances to the public and in the opinion of the panel this is not being observed. The report stated that 25 well-known brands of drugs that are potentially lethal, particularly in the hands of children or potential suicides, can be bought without a prescription. A person with suicidal intent can go into six drugstores in succession and purchase a lethal quantity of some of these drugs. Another hazard is the morbid dependence of some persons on such drugs. The committee believes that there is a strong case for making all of these drugs prescription items. The report also suggests that there should be a controlled survey to ascertain the extent of self-medication and that an independent body should be set up to test the claims of advertisers. Statements made about a drug or remedy often contain a reference to a "new" or "recently developed" substance with special properties. The precise nature or composition of the substance is seldom or never given, and the advertising material in such cases makes its appeal to the current worship of science.

Coronary Angiography.—Coronary angiography is being developed in the department of cardiology, St. George's Hospital, London. This is the only method of obtaining information on the condition of the coronary arteries during life. The ECG only reveals the condition of the heart muscle. It is desirable to detect narrowing and calcification of the coronary vessels in the early stages of the disease and to assess the value of operative procedures, diet, and anticoagulants in the treatment of coronary disease. Coronary angiography should also help in the selection of patients for operation. The procedure is carried out by advancing a catheter along the brachial artery until it is within an inch of the aortic valves. This is done under radiographic control with use of an image intensifier. The injection of radiopaque medium into the catheter is made against the aortic valves as the ventricles contract. It enters the coronary vessels and its course is followed by cineradiography.

CORRESPONDENCE

ALCOHOL AND MOTOR ACCIDENTS

To the Editor:—It has become increasingly obvious that the influence of alcohol is the most frequent human factor responsible for serious motorcar crashes. The records of Dr. S. R. Gerber at the county coroner's office, Cleveland, for the last 19 years show that 46% of the pedestrians, 54% of the drivers, and 42% of the passengers had been drinking. Since these figures include deaths up to 12 hours after the crash, Dr. Gerber points out that some of the victims tested had survived a sufficient length of time to metabolize alcohol present at the time of the "accident," and, therefore, contributed to the number of negative tests.

A recent study by Haddon and Bradess from Westchester County, New York, revealed that 87 drivers had died within four hours of their single-vehicle crash. Eighty-three, or 95%, of these had had blood alcohol level determinations. Of the 83, 73% had been drinking; 69% had blood alcohol levels over 0.05%, and 49% had levels of 0.15% or more. Figures from other widely scattered areas over the United States show similar percentages, and if this can be assumed to hold for the nation as a whole, about 50% of the 30,000 nonpedestrian deaths each year can be attributed to the drinking driver.

It has become accepted by the courts throughout the land that a driver whose blood alcohol level reads 0.15% or less is not "under the influence" of alcohol. This 0.15% reading means that, for a 150-lb. (68-kg.) person, 6 oz. of 100-proof liquor have been distributed throughout the blood, tissues, and brain. To attain this blood alcohol level, about 7 or 8 oz. need to be swallowed in about an hour; and this is 100-proof material, not the usual 86-proof or 90-proof.

Two events of significant impact on this problem have occurred in the last few months.

At the Indiana University Symposium on Alcohol and Road Traffic, Dec. 12-14, 1958, the following statement was prepared: "It is the opinion of this Committee that a blood alcohol concentration of 0.05% will definitely impair the driving ability of some individuals and, as the blood alcohol concentration increases, a progressively higher proportion of such individuals are so affected, until at a blood alcohol concentration of 0.10%, all individuals are definitely impaired." This was signed by a significant group of the outstanding authorities in the alcohol-motorcar field. At long last, the unrealistic figure of 0.15% may perhaps be displaced by a blood alcohol level more practically related to the role of the drinking driver in our traffic deaths and injuries.

A second important event is the publication by the American Medical Association of a Medical Guide for Physicians in Determining Fitness to Drive a Motor Vehicle (*J. A. M. A.* 169:1195-1207 [March 14] 1959). It is significant that the news services, in commenting on this new manual, devoted most of their space to the alcohol section.

With this recognition, the next need is implementation. The first step here is the passage of legislation by all states making it virtually certain that a driver suspected of driving after drinking be subjected to chemical tests to prove whether alcohol, or some other factor, is the cause of his unusual behavior. Five states, led by New York, and followed by Kansas, Idaho, Utah, and North Dakota, have taken this necessary step. Legislatures of some 20 other states have considered and, so far, have refused or neglected to enact this life-saving measure.

Nothing will so surely reduce the number of drinking drivers on our highways as prompt conviction for drinking charges, and nothing will so surely lead to conviction as incontrovertible, objective evidence of drinking while driving; but we need more than this. We need courts and prosecutors who will use the evidence at hand. At the moment, the weak link in the drinking-driving problem is the prosecution. The records of every state are replete with long case histories of drinking drivers who have had repeated arrests, only to be released, until they have killed themselves and one or more others in their final drinking-driving violation.

"NUCLEAR SEX"

To the Editor:—While determinations of "nuclear sex" by the techniques described in the editorial in The Journal, June 6, 1959, page 678, gave the first clues to the remarkable nature of cellular sex in Turner's and Klinefelter's syndromes, even more fundamental observations have been made recently and should be brought to the attention of those who read that editorial. These syndromes and mongolism are the first human diseases to be associated with the loss or addition of a chromosome. While previously unidentified in man, the effects of such abnormal karyotypes are well known in nonmammalian species.

The indirect methods of determining so-called nuclear sex have been able to distinguish between normal males and normal females, but the dichotomy fails in situations like Turner's and Klinefelter's syndromes. The sex chromosomes of such patients are neither those of the normal female (X X) nor those of the normal male (X Y) in all cases so far reported. The cells from patients exhibiting Klinefelter's syndrome have contained a Y and two X chromosomes (which raises the total number from 46 to 47). Cells containing but one sex chromosome, and that an X, giving a total of 45 rather than 46, have been found in Turner's syndrome.

Inferences, based on the presence of Barr chromatin (Barr and Bertram, *Nature* 163:676, 1949), such as, "the genetic sex has proved to be female in many of the clinically recognized cases [of Klinefelter's syndrome]," are now known to be incorrect. If Barr chromatin were reported to be "present" or "absent," rather than "male" or "female," such errors might be reduced. What is needed is exact information as to the numbers and kinds of chromosomes present. Those interested in disorders of human chromosomes or the diseases they produce should consult the papers and editorial which appeared in the *Lancet*, April 4, 1959; the correspondence in the April 18 and April 25 issues; and the references therein. The contributions of cytogenetics to our knowledge of man are just beginning.

SPONTANEOUS REGRESSION OF MALIGNANT DISEASE

To the Editor:—Your guest editorial on spontaneous regression of malignant disease, in The Journal, April 11, page 1758, stated that the theory for spontaneous regression of malignant tumors had not been advanced. The theory for disappearance can be evolved from the research work of biochemists Dulkin and Lobstein of the Research Foundation for Diseases of the Eye. They found that lysozyme, an enzyme found in body fluids and in tears, in addition to being bacteriostatic, is carcinostatic for certain tumors in rats. The work, which resembles Fleming's experiments with penicillin in the manner of procedure, is promising. Clinical trials have not been made.

Other body enzymes may also be carcinostatic. Experiments are planned to determine whether lens epithelium secretes carcinostatic substances. Cancer has not been reported in the lens. The progress of cancer is like that of other diseases—a struggle between host resistance and the virulence and degree of malignancy. The chief factor in host resistance may be lysozyme and other body enzymes.

MEDICAL FILM REVIEWS

HOSPITAL SEPSIS: A COMMUNICABLE DISEASE

The premiere showing of "Hospital Sepsis: A Communicable Disease" drew a capacity audience at the Annual Meeting of the American Medical Association, Atlantic City, June 8. This film, which was produced in cooperation with the American College of Surgeons, American Hospital Association, American Medical Association, and Johnson and Johnson, is now available from the A. M. A. Motion Picture Library for showing to physicians and hospital groups.

Portion of capacity audience at premiere showing of "Hospital Sepsis: A Communicable Disease."

Culdoscopic Technique and Cinematography: 16 mm., color, sound, showing time 19 minutes. Prepared by Albert Decker, M.D., and Irving H. Saxe, M.D., New York. Produced in 1958 by Audio Productions, New York, for and procurable on loan from Schering Corporation, Bloomfield, N. J.

The instruments, the position, and the step-by-step technique used in culdoscopic examination of a patient are demonstrated in this film. Representative pathology and normal pelvic anatomy as seen through the culdoscope are shown by means of an 8 mm. reflex camera. The pathology includes fimbrial adhesions, unruptured tubal pregnancy, tubal abortion, tubal peristalsis, appendicitis, and salpingitis. Not too much time is spent on technique, but it is adequate. Two patients are shown, followed by a number of examples of various types of ovarian, tubal, and uterine pathology. However, the whole procedure looks so smooth and readily done that the viewer is likely to get a wrong impression about the ease of the operation. This is an excellent film. The principles enunciated are sound, and the film is recommended to anyone interested in the procedure of culdoscopy.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Heart Failure in Patients with High Blood Pressure. J. N. Mickerson. Brit. Heart J. 21:218-224 (April) 1959 [London].

In an attempt to assess the causes of heart failure, a common complication and a major cause of death in patients with high blood pressure, the author studied 184 men and 157 women with hypertension, who were admitted in heart failure to the Charing Cross Hospital in London. A cause of heart failure in addition to hypertension was found in all but 10 (3%) of the 341 patients. Ischemic heart disease precipitated heart failure in 172 (50%) of the 341 patients, and in an additional 48 patients (14%) it probably contributed to the heart failure. Other important causes of heart failure were valvular lesions in 37 patients (11%), renal disease, alone or combined with cardiac lesion, in 50 patients (15%), respiratory infection in 20 patients (6%), and malignant hypertension in 29 patients (9%). The remaining less frequent causes of heart failure in 23 patients (6.6%) were combined to form a miscellaneous group. The presence of a renal lesion doubled the mortality rate and reduced by 12 years the average age at death when compared with patients without renal damage, whose average age at death was 66.1 years and among whom the mortality rate was 21%. Patients with evidence of renal disease had the highest blood pressures. The worsening prognosis of patients with hypertension and heart failure with rising blood pressure levels was shown to be due to the presence of a renal lesion rather than to the height of the blood pressure per se.

The Pulseless Syndrome. M. H. Lessof and L. E. Glynn. Lancet 1:799-801 (April 18) 1959 [London].

The authors are of the opinion that clinical case reports that have been published under the heading of "pulseless disease" describe a syndrome rather than a disease entity. Obstruction of the large arteries arising from the arch of the aorta may be due to several causes, including syphilitic aortitis, healed dissecting aneurysm, trauma, atheroma, and congenital vascular anomalies. Even when these conditions are excluded, the reported cases of arteritis of medium-sized and larger vessels do not always correspond with those in young Japanese women described by Takayashu in 1908. By common usage, pulseless disease implies an absence of pulses in the arms and sometimes in the neck, together with evidence of an inflammatory reaction, such as fever, increased erythrocyte sedimentation rate, and raised serum globulin level, or else histological evidence of arteritis near the origin of large vessels. These features were present in the 3 women reported, who ranged in age from 21 to 39 years. All 3 women presented with loss of pulses in both arms, but the underlying diseases were different. One had obliterating brachiocephalic arteritis of Takayashu; the second had an unidentified thrombotic condition of the large arteries; and the third had arterial occlusion associated with systemic lupus erythematosus. Blood flow studies in the limbs helped to define the extent of peripheral arterial involvement, even when symptoms were absent.

Some Patients with Unusually High Digitalis Requirement. P. Kirketerp. Ugesk. laeger 121:496-498 (March 26) 1959 (In Danish) [Copenhagen].

Kirketerp cautions against adherence to a standardized digitalis dosage. In the 5 patients reported, who had been seen over an 8-year period in a medical department of moderate size, the digitalis need was found to be 2 or 3 times that of the ordinarily used dose of 100 mg. of folium digitalis 6 times weekly. For these patients the larger digitalis dose meant a decisive change for the better in their clinical condition. The author advises the physician to bear in mind that now and then there will be a patient who is not helped by digitalis until he receives a dose essentially higher than that usually prescribed.

Differential Pulmonary Artery Occlusion in Patients with Chronic Pulmonary Disease. B. L. Charms, B. L. Brofman and A. Adicoff. Am. J. Med. 26:527-533 (April) 1959 [New York].

Five patients with pulmonary disease, either localized or generalized, were subjected to hemodynamic studies. The technique of balloon occlusion of first one and then the other of the main branches of the pulmonary artery was used. With

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

localized pulmonary lesions, occlusion of the pulmonary artery supplying that area diminished or abolished venous admixture due to a diminished local ventilation-perfusion relationship. Increase in flow through pulmonary lesions by occlusion of the opposite pulmonary artery caused an increase in venous admixture and further fall in systemic arterial oxygen partial pressure and hemoglobin saturation. Cardiac output, pulmonary artery pressure, and respiratory minute volume changes closely paralleled changes in arterial oxygen content. The method of temporary unilateral pulmonary artery occlusion proved to be a useful adjunct in evaluation of patients with pulmonary lesions, especially in determining pulmonary resectability when diffuse disease was also present. Pulmonary arteriolar and total pulmonary resistances were calculated with use of pressure distal to an occluding balloon; this is not necessarily the same as a control wedge pressure. Only small increases in resistance were observed with respect to the increase in flow produced in the unoccluded lung, and calculated resistance actually fell to approximately one-half of assumed control level.

Pulmonary Artery Stenosis. H. A. Shafter and H. A. Bliss. Am. J. Med. 26:517-526 (April) 1959 [New York].

The authors add 5 patients with stenosis of the pulmonary artery to the 28 previously described. The 5 patients were observed in the course of 18 months. Two had no other apparent lesions of the heart or great vessels; 3 had evidence, by catheterization of the right side of the heart, of ventricular septal defect, probable common atrioventricular canal, and patent ductus arteriosus respectively. None had pulmonic valve stenosis. A study of the 5 patients and a review of the literature reveal some helpful clues to the diagnosis, and raise important questions about the etiology, physiological significance, and treatment of this lesion. The clinical diagnosis of pulmonary artery stenosis is frequently hampered by coexistent cardiovascular lesions. A continuous murmur should make one think of the diagnosis. The lesion commonly produces a systolic murmur, which may be heard with maximal intensity at the base of the heart several centimeters lateral to the sternal border. Pulmonary artery pressure rises abruptly when the cardiac catheter is withdrawn through the narrowed segment. In the absence of pulmonary artery narrowing, patent ductus arteriosus probably does not produce such a pressure change. The appearance of a constantly narrowed pulmonary artery segment on angiocardiographic study strengthens the diagnosis.

Although pulmonary artery stenosis may in most patients originate as a developmental anomaly in fetal life, the possibility that it occasionally occurs as an acquired lesion at some time after birth must be examined. Some evidence suggests that either pulmonary artery thrombosis or "natural transformation" of the pulmonary artery resulting from prolonged rapid pulmonary blood flow may occasionally produce pulmonary artery stenosis. The term "natural transformation" was used by Gasul and associates in describing the narrowing of the right ventricular outflow tract which, developing gradually over a number of years, may reduce the left-to-right shunt in patients with ventricular septal defect. One may inquire whether or not the prolonged increase in pulmonary blood flow in other patients with left-to-right shunt may in time produce "natural transformation" of the pulmonary artery, i. e., pulmonary artery stenosis, with consequent lessening of the shunt.

The physiological significance of stenosis of the pulmonary artery depends upon the resistance it offers to right ventricular outflow. Resistance mainly depends upon the physical characteristics of the narrowing, i. e., upon its length and lumen. A lesion causing only a small pressure gradient at rest may with exercise produce significant right ventricular hypertension. In most patients, pulmonary artery stenosis does not cause serious hemodynamic abnormalities. If these are present, however, surgical repair may be possible and desirable.

Neuroendocrinic Syndromes in the Course of Tuberculous Meningitis. L. Pertoni and R. Bistaffa. Riforma med. 73:327-331 (March 21) 1959 (In Italian) [Naples].

Neuroendocrinic syndromes were observed in 4 of 49 patients with tuberculous meningitis seen by the authors between 1948 and 1957. The first patient, a 29-year-old woman, some weeks after clinical recovery from the meningitis and dismissal from the hospital, complained of an abnormal and marked libido which lasted for a few months. The second patient, a 13-year-old boy, while recovering from the meningitis after months of treatment, suffered polydipsia and polyuria; a diagnosis of diabetes insipidus was made, and the patient recovered from the latter disease after a period of about 2 years. The third patient, a 21-year-old man, died 8 months after admission to the hospital; on autopsy, signs of pulmonary tuberculosis, meningeal irritation, and a caseous focus in the right adrenal gland were observed. The fourth patient, a 17-year-old youth, 6 months after treatment, while showing signs of recovery from the meningitis, suffered bulimia which disappeared after a few months. The authors believe that in the first and fourth patients the neuroendocrinic syndromes were the result of streptomycin given for the treatment of tuberculous meningitis; streptomycin, acting as a stimulant, caused a hyperfunction of the diencephalon and of the adrenal gland; the syndromes regressed with the suspension of treatment. In the second patient the neuroendocrinic syndrome was more likely connected with the process of a basal arachnoiditis.

Some Pathogenetic and Clinical Aspects of Pulmonary Tuberculosis with Respect to Intercurrent Influenza Episodes. N. Montanini, G. Pallotta and G. De Ritis. Ann. Ist. Carlo Forlanini 18:370-384 (no. 4) 1958 (In Italian) [Rome].

The relationship between pulmonary tuberculosis and influenza was studied in a group of 43 patients with tubercular pulmonary lesions, at different clinical and roentgenologic stages, who contracted Asian influenza in 1957. In most patients the influenza reactivated the apparently inactive tubercular lesions; relapses occurred in some patients who had been dismissed from the hospital for a long time either because they had clinically recovered or because their condition was stationary. None of these patients at the moment of contracting influenza was taking tuberculostatic drugs. Influenza had no effect on the condition of hospitalized patients with active pulmonary tuberculosis who were being treated with antibiotics; they were deriving benefit from the treatment and showed no resistance to the drugs. Influenza, however, caused death in most chronic tuberculous patients who showed resistance to all antibiotics. The authors believe that treatment with isoniazid should be continued periodically, and for a long time, until there is complete recovery in patients who have recovered only clinically or whose condition is stationary. Treatment with isoniazid is necessary in case these patients should contract virus infections.

The Volume of N/10 Hydrochloric Acid Neutralized Per Day in the Treatment of Peptic Ulcer. E. A. Marshall and D. Samon. Am. J. Gastroenterol. 31:389-397 (April) 1959 [New York].

The authors observed 3,877 patients with roentgenologically confirmed peptic ulcer. Nine hundred ninety-two of these patients had had hemorrhages one or more times before being seen; 430 had nonstenotic obstruction; and in 159 the ulcer had previously perforated. Complications had been encountered in 1,582 patients, and the remaining 714 had symptoms of uncomplicated ulcer. Treatment was based especially on the consideration that at least 14 liters of N/10 hydrochloric acid must be neutralized each day in order to inactivate the corrosive effects of acid in peptic ulcer and permit the patient to ingest an unrestricted diet without symptoms. For neutralization the authors depended on aluminum hydroxide and calcium carbonate. The medicaments were administered at half-hour intervals for 16 hours a day, at bedtime, and 2 and 4 hours after retiring. This schedule was not changed for 4½ months. The use of the roentgenogram as a criterion of the healed ulcer was regarded as inadequate. A patient who upon completion of the intensive medical treatment was able to ingest a completely unrestricted diet for more than a year without symptoms, and without any subsequent antacid medication, was considered to have a healed ulcer. A patient who 24 hours after initiation of a program of sufficient sedative, alkalizing, and adsorptive drugs was able to ingest a completely unrestricted diet without distress was presumed to have a "healing" ulcer. Treatment resulted in healing in 83.4% of the 3,877 patients. The remaining 16.6% required that 19.5 liters of N/10 hydrochloric acid or 71 Gm. of pure hydrogen chloride be neutralized each day; two-thirds of these (7.6% of the total group) were therapeutic failures. Follow-up studies on 1,278 patients showed that most of them remained healed for 3 or more years.

Epidemiologic and Clinical Observations in Sarcoidosis. M. M. Cummings, E. Dunner and J. H. Williams Jr. Ann. Int. Med. 50:879-890 (April) 1959 [Lancaster, Pa.].

Sarcoidosis was diagnosed in 1,700 patients seen in Veterans Administration hospitals between 1949 and 1956. The case records of 1,194 of these patients whose conditions were diagnosed during the 5-year period 1949-1954 were reviewed. Information concerning age, race, sex, place and date of birth, and place of initial hospitalization was analyzed. The most striking observation was the geographic distribution of the disease, revealing an endemic area in New England and the North Central States. The rural location of birthplace and the predominance among Negroes, observed by Michael, were confirmed in this study. The distribution of birthplaces of veteran patients given a diagnosis of sarcoidosis correlated better with a pine forest environment than it did with the sandy soil suggested by Gentry. Lumbering and wood milling were designated as the leading industries in the high sarcoidosis prevalence areas.

A detailed clinical analysis of 256 records selected at random from those of the 1,700 patients was then undertaken. This was done to evaluate the diagnostic criteria utilized in widely scattered hospitals, and to learn more about the natural history of the disease. The criteria used for diagnosis in the study of the 256 records are those defined by a subcommittee of the National Research Council in 1956. According to these, sarcoidosis is a systemic disease, or group of diseases, of undetermined etiology and pathogenesis. Histologically, it is marked by the presence of epithelioid-cell tubercles, showing little or no necrosis. Varying types of inclusions in giant cells may be present but are not pathognomonic. A similar histological picture may be found in certain other diseases, especially in infectious granulomas and in beryllium poisoning. Clinically, the disease most commonly involves lymph nodes, lungs, skin, eyes, liver, spleen, and phalangeal bones. The course is usually chronic, and constitutional symptoms vary. While the intracutaneous tuberculin test is frequently negative, a positive test does not controvert the diagnosis.

When an effort was made to apply these criteria more critically than the reporting hospitals had done, 81 cases were eliminated, and 175 cases, in which biopsy had confirmed the diagnosis, were studied further. As classified by race, 76 patients were white, and 99 nonwhite. Since 10% of American veterans are Negroes, the frequency of sarcoidosis among Negroes was 12 times greater than among whites. It was learned that sarcoidosis with biopsy confirmation may still at times be confused with other diseases, particularly those which may lead to granulomatous reactions. Sarcoid reactions to neoplastic diseases, as well as to tuberculous or fungous infections and beryllium disease, must be kept in mind. Sarcoidosis does not appear to be so benign as is generally reported. A follow-up study revealed that 15% of the veterans with sarcoidosis died within a 5-year period. The most frequent cause of death was cor pulmonale. Active tuberculosis was a not infrequent finding. Certain laboratory findings suggested that pine pollen may be added to the list of agents thought to be responsible for the disease or syndrome, sarcoidosis.

The Clinical Value of Renal Biopsy. D. J. Deller, V. J. McGovern and R. Reader. M. J. Australia 1:481-486 (April 11) 1959 [Sydney].

The authors report on 53 aspiration renal biopsies performed successfully on 51 patients after 59 attempts. Renal tissue was obtained from the cortex and medulla in 52 cases and from the medulla only in 1. The average number of glomeruli contained in a biopsy specimen was 16. Certain difficulties in technique are discussed, but, in general, they were not great. Complications after renal biopsy were uncommon. In one patient necrotizing papillitis occurred and required nephrectomy. In 2 patients a preexisting infection appeared to be aggravated. The relationship between biopsy and these complications is not clear. The clinical diagnosis was confirmed by biopsy in 22 of the 51 patients; the clinical diagnosis was compatible with the histological findings in 10; the clinical diagnosis was changed as a result of biopsy in 13; and in the remaining 6 neither the clinical nor the biopsy features were sufficiently characteristic to be of definite significance. The diseases which biopsy showed to be present most frequently, when not thought likely clinically, were either chronic pyelonephritis or chronic glomerulonephritis.

Renal biopsy may be of value in the management of patients with the nephrotic syndrome, hypertension, and miscellaneous renal diseases. An etiological diagnosis may be provided by biopsy in patients with the nephrotic syndrome, and the severity of the lesion assessed. Information of value concerning prognosis and therapy may be obtained. In patients with hypertension, renal biopsy can usually confirm or exclude chronic glomerulonephritis. Renal biopsy led to an unexpected diagnosis in 5 patients with obscure renal disease, as follows: 1. Focal embolic glomerulonephritis was shown in one patient in whom the diagnosis of subacute bacterial endocarditis had not been seriously considered. 2. The presence of moderately severe diabetic glomerulosclerosis in a young woman with diabetes mellitus, who was clinically well and desired a pregnancy, modified the physician's approach to her case. 3. Chronic glomerulonephritis was revealed in a boy with a symptomless proteinuria, and this finding helped the general physician in the advice he gave to the child's parents. 4. Lupus nephritis was strongly suggested by renal biopsy in a young woman with a clinical diagnosis of pyelonephritis. 5. Renal biopsy disclosed normal tissue in a woman 5 months pregnant who was considered clinically to have chronic glomerulonephritis and who progressed to term without complication.

Renal biopsy has a definite but limited value in clinical practice. It is no substitute for the more usual diagnostic procedures and techniques, and must be considered in the light of these methods. It is not a short cut in the diagnosis of renal diseases, for problems arise in sampling and pathological interpretation.

Treatment of Acute Hemorrhagic Pancreatitis with Cortisone. C. Lacerenza. Minerva chir. 14:305-309 (March 15) 1959 (In Italian) [Turin, Italy].

The cases of 6 patients, ranging in age from 28 to 52 years, with acute hemorrhagic pancreatitis are reported. Four patients were male, and 2 were female. After surgical treatment each patient received antibiotics and 100 to 200 mg. of cortisone per day. A pancreatitic relapse was suspected in the first patient, and the symptoms were checked with antibiotics and cortisone. After this patient suffered a third relapse, treatment with cortisone was not as effective as during the previous 2 courses, but his clinical condition improved markedly and rapidly. One patient, a 28-year-old woman, died of acute yellow atrophy of the liver after choledochostomy and cholecystectomy. Antibiotics in another patient, a 43-year-old woman, caused diarrhea which provoked a sudden diminution of the diuresis; this complication was checked with 15 units of human plasma and erythromycin. Cortisone had a good effect on the symptoms in all the patients and caused a marked drop in the serum amylase. The blood sugar level, which was high in some patients, became normal in a few days. The drug was also effective in relapses.

Corticotropin (ACTH) and the Adrenal Steroids in the Management of Ulcerative Colitis: Observations in 240 Patients. J. B. Kirsner, W. L. Palmer, J. A. Spencer and others. Ann. Int. Med. 50:891-927 (April) 1959 [Lancaster, Pa.].

The authors summarize their experience with corticotropin (ACTH) and the adrenal steroids in ulcerative colitis during the period from January, 1950, to November, 1957. The series comprised 240 patients, each of whom had been under observation for at least one year; none had responded satisfactorily to conventional medical management. The patients included 128 males and 112 females, mostly in the younger age group. The colitis had been of long duration, exceeding 5 years in 168 of the patients. Roentgenologic evidence of colitis was demonstrated in most patients, involving the entire colon in approximately 50% of them. Complications had preceded steroid therapy in 210 of the 240 patients. Blood transfusions had been required in approximately one-half of the series; approximately 100 patients had been advised elsewhere to undergo colectomy and ileostomy. The colitis was classified as mild in 12 patients, moderate in 86, and severe in 142. The objectives of therapy included the reestablishment of normal intestinal function, the restoration of nutrition, and the resumption of a normal life. The over-all response to combined medical and steroid therapy was classified as good in 115 patients, moderately favorable in 80, and minimal in 45.

Corticotropin, given intravenously and intramuscularly, was the most potent compound, followed by intravenously administered hydrocortisone. In oral administration, however, prednisone and prednisolone surpassed hydrocortisone on a milligram basis in a ratio of 2:1, the therapeutic effects being approximately similar with such doses. A favorable response consisted of the rapid disappearance of fever, toxemia, bloody diarrhea, and abdominal discomfort; appetite improved, and there was an increased sense of well-being. Proctoscopic improvement occurred more slowly than did the clinical response. Laboratory indications of improvement were the return of elevated sedimentation rates to normal, disappearance of blood from the stools, improvement in the anemia, restoration of normal patterns of plasma proteins, and, in serial biopsies, histological evidence of healing.

Steroid therapy has been continued in 101 patients; in 63 of these remissions persist, but there have been recurrences, often less severe than previously, in 38. The steroids have been considered to be very helpful in 46, helpful in 48, and ineffective in 7 instances. Eighty-nine patients are leading useful lives, while 12 are variously incapacitated but are not invalids. Steroid therapy has been discontinued in 99 patients, 59 of whom experienced recurrences. Remissions have been sustained in 40 cases, lasting longer than one year in 37. Steroids have been judged as very helpful in 47 persons of this group, helpful in 28, and ineffective in 24; 86 persons are leading effective lives, while 13 are variously incapacitated. The most important problems were emotional difficulties in 40 patients (including 3 suicides), infections in 43, and severe hypercorticism in 35. Perforations of the small intestine and peritonitis occurred in 2 patients. Surgery was necessary in 26 patients (11%). The indications were as follows: minimal or decreasing response to medical treatment, 10 cases; fulminating disease, 5; uncontrollable hemorrhages, 4; possible carcinoma, 2; polyps, 2; resection of apparently localized disease, 2; and intestinal obstruction, 1. Twenty of the 26 patients operated on survived. Twenty-three patients (9%) died, 6 of causes related to the colitis, 7 of complications associated with steroid therapy, and 10 of causes unrelated to ulcerative colitis or the use of steroids. Corticotropin and the adrenal steroids (hydrocortisone, prednisone, and prednisolone), though not curative, are highly effective adjuncts in the treatment of ulcerative colitis. The effects of the steroids surpass the response to any other therapeutic procedure.

Sacro-Iliitis in Reiter's Disease. J. K. Oates and A. C. Young. Brit. M. J. 1:1013-1015 (April 18) 1959 [London].

The authors report on 76 men and 2 women with Reiter's disease, 46 of whom had suffered more than one attack of the disease. All the patients had arthritis involving one or more joints associated with urethritis. Some of the patients also had conjunctivitis or iritis. Involvement of the sacroiliac joints was revealed by roentgenologic examination in 35 patients (44%). Nine patients (11.5%) showed doubtful evidence of roentgenographic abnormality of the sacroiliac joints, and 34 (43.6%) had roentgenographically normal joints. Sixteen (45.6%) of the 35 patients, 3 (33%) of the 9 patients, and 5 (14.7%) of the 34 patients complained of backache. Twelve (34%) of the 35 patients had iritis, compared with only 3 (8.8%) of the 34 patients. The attacks of iritis were recurrent in 9 of the 12 patients and were usually the only manifestation of the disease.

Sacroiliac disease revealed roentgenographically is common in patients with Reiter's disease. Clinically, appreciable involvement of these joints is probably common only during the acute stages of the disease, but the diagnosis may be easily missed. In patients with Reiter's disease special attention should be paid to the presence, site, and distribution of backache. Sacroiliac disease in this condition often appears to be associated with recurring attacks of iritis. This iritis is usually the only symptom. The occurrence of frequent attacks of iritis in men should always lead to inquiry into the presence of a past history of Reiter's disease or its components. Evidence of sacroiliac disease and genital infection should be carefully sought in such patients.

SURGERY

The Dynamic Pharyngeal Flap: Its Selective Use and Electromyographic Evaluation. T. R. Broadbent and C. A. Swinyard. Plast. & Reconstruct. Surg. 23:301-312 (April) 1959 [Baltimore].

Good speech is the goal in the management of any anatomic or physiological abnormality of the palate. The pharyngeal flap has received considerable interest, but its use as a dynamic muscular unit, rather than a static bridge, has not been clarified. The investigations described extended over a 4-year period and were designed to demonstrate the functional or static nature of the pharyngeal flap. The preoperative and postoperative management and the basic operative procedure have been described and illustrated by earlier investigators whom the authors mention in a historical review. Some aspects of the procedure are commented on by the authors, who performed pharyngeal flap operations on 49 patients. Speech deficiency was caused by cleft palate in 35 patients, and in the other 14 the speech defect was due to congenital paresis, to hemiplegia, to postoperative or postinfectious paresis, to poliomyelitis, or to postoperative defect in the palate.

The operation is done under general, transnasal, endotracheal anesthesia. Nasal intubation affords greater working space within the mouth and pharynx than oral intubation and also allows for attachment of the flap to the posterior palatal surface with greater ease. The endotracheal tube can be shifted from side to side, gently, easily, and safely, without the production of laryngeal edema, during elevation of the flap. During attachment of the flap, the tube occupies one posterior nasal aperture without producing abnormal tension on the flap. The selected use of the flap will determine its length, width, and position of its base. Lateral incisions are made on either side of the posterior pharyngeal wall, and the mucosa and the posterior pharyngeal fascia and superior constrictor muscle are spread through to the glistening white prevertebral fascia. This bipedicle musculomucosal flap is elevated away from the prevertebral fascia with a right-angle scissors. One end of the flap is cut across, preserving either a superior or an inferior pedicle as desired. A superior pedicle was used in 16, and an inferior pedicle in 33 of the 49 patients operated on for speech defect by transfer of a pharyngeal flap to the posterior palate. A healthy section of superior constrictor muscle was included in all the flaps.

The authors describe a method of electromyographic evaluation of the muscular activity of the palatopharyngeal tissues. In all the pharyngeal flaps tested (superior pedicles and inferior pedicles), normal motor units were demonstrated. The palatal muscles were individually and simultaneously tested for comparative purposes. Similar electromyographic patterns in voltage, frequency, and wave form were noted in the pharyngeal flap as well as in normal tensor palatini, levator palatini, and the superior constrictor. On the basis of these studies it is felt that the pharyngeal flap is a dynamic muscular unit. Selective planning of the width, location, and position of the flap and its pedicle, as well as its point and extent of insertion, affords more suitable and wider application of the pharyngeal flap to anatomic defects and physiological paresis, as well as to cleft palate problems.

Symptomatology and Therapy of Bronchial Adenomas. H. Reitter. Ztschr. Tuberk. 112:257-272 (no. 5-6) 1959 (In German) [Leipzig, Germany].

The author reports on 8 male and 11 female patients, between the ages of 15 and 63 years, with bronchial adenoma who were admitted to the surgical clinic of the Medical Academy in Duesseldorf, Germany, between 1951 and 1958. These 19 cases of bronchial adenoma were observed among 1,800 cases of bronchial and pulmonary tumors in the last 10 years. In 11 of the 19 patients, the tumor was localized at the points of origin of the lobal bronchi; in 5, in the main bronchus; and in 3, in segmental bronchi. The duration of symptoms which preceded the diagnosis varied from 2 months to 30 years. The characteristic main symptoms during the first stage of the disease were recurrent hemoptyses and chronic, dry, irritative cough. These symptoms were observed in 16 of the 19 patients, and 13 of them had hemoptyses. The second stage of the disease was characterized by progressive bronchial stenosis with resulting atelectasis, chronic pneumonia, and abscesses; these secondary changes of the parenchyma, rather than the tumors as such, induced the patients to consult a physician. Early diagnosis is imperative in order to prevent such irreversible pulmonary changes. Although chest roentgenograms and tomograms may reveal the tumor in only 20% of the cases, the diagnosis of bronchial adenoma can be established with the aid of bronchoscopy and exploratory excision followed by microscopic examination.

Surgical treatment is the method of choice, and bronchoscopic removal of the tumor should be omitted because of the highly increased risk of recurrence. Eighteen of the 19 patients were operated on; one patient was not operated on because of amyloidosis. Of the 18 patients, 7 had lobectomies, 6 pneumonectomies, 3 segmental resections, and 2 bilobectomies. The local removal of the tumor by bronchotomy, resection of the bronchus, or segmental resection is rarely sufficient, and pneumonectomy and lobectomy are required in most patients because of secondary parenchymal damage. There were 2 operative deaths, representing a mortality rate of 11%. Two patients died within 2 months after the operation, and malignant changes occurred after one year in one patient. Fourteen patients obtained satisfactory results, and 2 had recurrences within 5 and 6 years after the operation. Careful postoperative control is required, since local occurrences are to be expected in 10% of the patients and malignant changes in an additional 10%. In case of recurrence, thoracotomy should be repeated with radical removal of the tumor. The prognosis of such a repeated operation is favorable. Metastases of bronchial adenomas are rare, but may occur with tumors of the carcinoid type. Metastases are not to be considered as contraindications to surgical treatment; solitary secondary tumors may be successfully removed surgically.

Some Observations Regarding 905 Patients Operated upon for Protruded Lumbar Intervertebral Disc. J. Raaf. Am. J. Surg. 97:388-399 (April) 1959 [New York].

Low-back and sciatic pain remains a complicated problem. To learn more about the results obtained with surgery, the author reviewed the case histories of 817 patients operated on by himself and of 88 patients operated on by his associates during the last 20 years for protruded lumbar intervertebral disk. A total of 954 operations for protruded disks were performed on these 905 patients. Protruded intervertebral disks were found in 76.2% of the 819 patients on whom the first operation for protruded disk was performed by the author or his associates; lesions about the nerve root other than disk protrusion were found in 5.5% of the patients; and no gross nerve root lesions could be found in the remaining 18.3%. Single protruded disks were found in 610 patients. Herniations of the nucleus pulposus were found in 558 of these 610 protrusions; 36 protrusions of the annulus were thought to be the cause of symptoms; and in 16 instances both annulus and nucleus pulposus were herniated. In 14 patients in whom 2 protrusions were found, 24 were herniations of the nucleus pulposus and 4 were protrusions of the annulus.

More than two-thirds of the patients were between the ages of 30 and 50 years. A fifth of the patients were women. About 70% of the patients gave a history of definite back injury. In comparing the symptoms, signs, and laboratory and roentgenologic findings in the 3 groups of patients, it was found that there were no significant differences between those with protruded disks, those with other nerve root lesions, or those without gross root lesions. However, a decrease in the achilles tendon reflex was found more often in patients with a protruded disk at the level of L-5 to S-1, and a decrease in the patellar reflex was found more often in those with protruded disks at the L-3 to L-4 space. Roentgenographic evidence of narrowing of a disk space could not be relied upon as evidence of a protruded disk.

Clinical judgment based on evaluation of the symptoms, signs, and laboratory and x-ray findings, exclusive of the Pantopaque test, was 82% accurate in making the diagnosis of protruded lumbar intervertebral disk. The Pantopaque test in 765 patients was proved to be 82% accurate. Clinical diagnosis and the Pantopaque test were simultaneously correct in 72% of 765 patients explored for protruded disk; both were incorrect in 7%; the clinical opinion was correct and the Pantopaque study incorrect in 11%; the Pantopaque study was correct and the clinical opinion incorrect in 10%. The over-all results of surgery in the patients operated on for protruded lumbar intervertebral disk were excellent in 43%, good in 37%, fair in 14%, and poor in 6%. In patients receiving compensation the results were claimed to be less satisfactory than in those not receiving a permanent partial disability award at the time their condition became stationary. The best results were obtained when a protruded disk was removed and no spinal fusion was deemed necessary. Surgical complications were few, and there were no operative deaths.

Complications of and Surgical Treatment for Primary Tuberculosis in Adults. P. Szigeti and M. Fráter. Ztschr. Tuberk. 113:12-19 (no. 1-2) 1959 (In German) [Leipzig, Germany].

A review of the literature on primary tuberculosis in adults and children and the authors' observations on adult patients with primary tuberculosis showed that complications of primary tuberculosis and the tendency of primary tuberculosis to progression occur more frequently in adults than in children. The authors have subdivided their adult patients with primary tuberculosis into 2 main groups. The first group consisted of patients with tuberculous lymphadenitis, the clinical aspect of which was predominated by enlargement of the bronchopulmonary lymph nodes. In this group were patients with segmental or lobal atelectasis which resulted from obstruction or perforation of an enlarged bronchopulmonary lymph node. The case of a 24-year-old woman with this form of primary tuberculosis is reported. On admission to the Johannis Hospital in Budapest, the patient's sputum was positive, and roentgenographic and bronchoscopic examinations revealed a compression stenosis of the Nelson type and atelectasis of the 6th segment. In the course of one year, during which the patient was hospitalized and was given antituberculous chemotherapy, the lymph node shrank, and the atelectasis subsided. This observation showed that regression of epituberculotic complications, which are caused by bronchopulmonary lymph nodes in adult patients, can be achieved by persistent administration of drugs, although it may be difficult and may take considerable time to exert an effect on the lymph node component.

The second group consisted of patients, whose primary tuberculosis was characterized by a complication in the peribronchial lymph node and in the parenchymal focus (primary complex). Two cases with complications of this type are reported. In the first, the bronchopulmonary lymph node perforated slowly into the bronchus, causing primary bronchogenous dissemination by way of a fistula, with resulting small and moderately sized foci in the lower lobe. The second case occurred in a 20-year-old woman a few weeks after delivery; the primary tuberculosis was resistant to drug therapy, and progression occurred in the peribronchial lymph node of the hilus and in the parenchymal component of the primary complex. To prevent further progression, total resection was carried out of the lymph node and of the 6th segment containing the parenchymal focus which showed irreparable fibrocaseous changes. Plastic surgery of the intermediate bronchus was done. Primary healing occurred, and the patient made a complete recovery. Surgical treatment thus can be successful in adult patients with primary tuberculosis resistant to drug therapy.

Intestinal Angina: Report of a Case with Preoperative Diagnosis and Surgical Relief. W. P. Mikkelsen and J. A. Zaro Jr. New England J. Med. 260:912-914 (April 30) 1959 [Boston].

The authors report on a 62-year-old man in whom for 2 years abdominal pain had occurred intermittently after meals, being occasionally associated with and relieved by vomiting. The pain was of a squeezing, bloating character and centered in the upper and right portions of the abdomen. Although it did not occur after every meal, a heavy meal was especially likely to precipitate it. Establishment of the correct diagnosis of "intestinal angina" (a term which most clearly identifies a syndrome of "work" intestinal ischemia which may, for months or years, precede complete occlusion of the mesenteric artery) was facilitated in this patient by the presence of advanced occlusive disease of the abdominal aorta. However, the "food-pain" relation was distinct. A weight loss of 50 lb. (22.7 kg.) had occurred. All laboratory tests and the usual x-ray studies yielded normal results.

At surgical intervention, complete abdominal exploration was negative in this patient, with the exception of the following vascular abnormalities. Occlusion of the abdominal aorta started at a level just below the renal arteries and extended to the external iliac arteries bilaterally. The inferior mesenteric artery was occluded. The superior mesenteric artery and its intestinal branches were pulseless; nor was a thrill palpable in this vessel or its branches. A thrill, though, was palpable in both the hepatic and the splenic arteries, but an expansile pulse was absent in both these vessels. Whereas ostial atherosclerosis existed, the principal cause of the obstruction of the superior mesenteric artery proved to be encasement of its first few centimeters by periaortic cicatrization. Successful liberation and endarterectomy of the superior mesenteric artery were carried out. During the 2 months after operation the patient gained 8 lb. (3.6 kg.) in weight, the symptoms of anginal pain were completely relieved, and postcibal distress completely disappeared. A longer postoperative follow-up will be required, though, to evaluate accurately this patient's response to the surgical treatment.

It is believed that the case of this patient is the first one in which the diagnosis of intestinal angina was recognized preoperatively and in which elective surgical treatment was successful. A heretofore unrecognized mechanism of impediment to the blood flow through the superior mesenteric artery was observed. Complete relief from the symptoms of intestinal pain followed surgical correction.

Treatment of Chronic Coronary Insufficiency with Bilateral Ligation of the Internal Mammary Artery. V. I. Kolesov, Y. N. Vishneevska, A. I. Drevina and E. A. Tsalolihhina. Vestnik khir. 82:33-41 (April) 1959 (In Russian) [Leningrad].

Animal experiments (on dogs) demonstrated that the internal mammary arteries anastomose with those of the pericardium and myocardium. Fifteen patients with coronary insufficiency of high degree were subjected to ligation of both internal mammary arteries. Most of these patients had suffered attacks of anginal pain for many years and were invalids. Nine of them had had a myocardial infarction, and 5 of them had it twice. Medical therapy failed to bring about any improvement. The follow-up of 10 of the 15 patients revealed that they were free from attacks of anginal pain or that they suffered from them rarely. The anginal pains were not as long lasting as they were previous to the operation. The conditions of 2 patients were not improved. Of the 13 patients who had good results, 12 remained improved, while one relapsed into the previous condition. The favorable clinical effect of the operation was corroborated by electrocardiographic changes which showed an improvement in coronary blood circulation.

Disseminated Lupus Erythematosus of the Alimentary Tract. J. Bruce and W. Sircus. Lancet 1:795-798 (April 18) 1959 [London].

The 27-year-old woman whose case is presented had 11 attacks of intestinal crises between May, 1955, and her death in April, 1958. During the first attack a presumptive diagnosis of appendicitis was made, and laparotomy was performed. The abdominal cavity contained about 3 pt. of clear yellow fluid. The small intestine was diffusely congested, and a few mesenteric nodes were enlarged. The appendix and other viscera appeared normal, but appendicectomy was carried out. Nausea and vomiting continued after the operation, and gastric aspiration and intravenous administration of fluid and electrolytes were needed. The temperature remained elevated (102 F), and an erythrocyte sedimentation rate (E. S. R.) of 65 mm. in one hour was noted. Intermittent pyrexia continued until discharge, and the E. S. R. remained at 100. Because of profuse diarrhea, central abdominal colic, and repeated vomiting, the patient was readmitted the day after discharge. The abdomen was distended and tender, and bowel sounds were absent. Vomiting continued, and hiccups and dehydration necessitated gastric suction and intravenous therapy. Examination with the aid of a barium meal showed coarse jejunal mucosa with irregular dilatation of the intestinal loops. Repeated blood cultures and fecal cultures were negative, and all serum agglutination reactions, including Brucella and Paul-Bunnell tests, were likewise negative.

A third attack shortly after discharge responded to drip and suction treatment. At a 4th attack about 6 months later, the uncertainty of the diagnosis and the severity of the attacks were considered to justify a laparotomy. Free fluid was again present in the abdominal cavity. The jejunum was grossly abnormal. The loops were heavy, intensely congested, and of a deep plum color. The mesentery was congested and edematous, and the mesenteric nodes were enlarged. Subserous ecchymoses appeared wherever the intestine was handled. The 5th attack of intestinal obstruction came 16 days later and was again severe enough to warrant admission. At later attacks swelling of the joints and mental symptoms appeared. Rubbery, enlarged nodes became palpable in the axillas and groins. Later liver function tests were found to be abnormal. During the 9th attack of intestinal obstruction, drip and suction therapy were again employed, and L. E. cells were now found in the peripheral blood.

At autopsy histological studies revealed acute and chronic vascular lesions of disseminated lupus erythematosus throughout the length of the alimentary tract.

Osler, in 1895, reported 11 cases of erythema exudativum multiforme, in all of which gastrointestinal crises—abdominal colics, usually with vomiting and diarrhea—were part of the disease. In the ensuing half century involvement of the digestive tract in disseminated lupus erythematosus, as the disease became known, was frequently noted, but little was known about the pathological basis of the alimentary symptoms. The authors feel that recurrent attacks of transient acute intestinal obstruction with segmental ileus in young subjects, especially women, with diarrhea accompanied by pyrexia and leukopenia, should suggest the diagnosis of intestinal lupus erythematosus, even in the absence of other recognizable phenomena of the systemic disease. At laparotomy, swollen, soggy, deeply injected lengths of small intestine are characteristic. The only difficulty in diagnosis—the differentiation between recurrent Crohn's disease and jejunitis acuta—may be resolved by observing the transient nature of the attacks, with either spontaneous resolution or rapid improvement on treatment with steroids or antihistamines.

Experience with Gastric Resection by the Péan-Rydygier-Billroth I Method. E. Polák and Vojtíšek. Ann. Surg. 149:475-480 (April) 1959 [Philadelphia].

The authors cite the merits of the gastric resection methods of the Polish surgeon, Rydygier, and the Czech surgeon, Jedlička, as treatment for gastroduodenal ulcer. Rydygier was the first surgeon to resect a stomach for stenotic pyloric ulcer, and Jedlička provided the first extensive statistics showing 3% mortality. The authors prefer the Péan-Rydygier method of resection on the basis of more than 30 years' experience. This method, in which the duodenum along the greater curvature is anastomosed to the stomach, seems to give the best results and is no more difficult than the Billroth II method, if the ulcer is removed.

The authors studied the occurrence and the significance of recurrence of ulcers in patients operated on at the surgical clinic of the Medical Faculty of Hygiene in Prague over a period of 20 years. After the original resection by the Péan-Rydygier method there were 0.65% recurrences; after the Billroth II resection, 0.4%; and after palliative resection without excision of the ulcer, 1.4%. Although it seems easier to perform operative correction after the Péan-Rydygier resection than after the Billroth II resection, the former resection also has its contraindications when the necessary conditions are not present for the possibility of end-to-end anastomosis. The chief contraindications are as follows: 1. The duodenum is not suitable for anastomosis because it is scarred or altered by a deeply penetrating and large ulcer on the posterior wall. 2. The position of the ulcer, with fixed cardia and immobile duodenum, is too high, so that suture cannot be made without tension. However, gaining a sufficiently large duodenal stump depends to a certain degree on the experience of the operating surgeon; the more experienced he is, the more rarely must he turn to a blind closure of the duodenum. The second contraindication is even more relative. Usually it is possible to leave a sufficiently large stump along the greater curvature, and the duodenum can be easily mobilized after incision of the peritoneum along the lateral wall pars descendens duodeni, so that suture end to end can be made without tension.

The individual listing of operations made by the senior author of this paper during the last 3 years was compared with those performed by all other surgeons at the clinic. This surgeon has achieved 90% operability with the Péan-Rydygier method, the mortality being under 1%. His co-workers have achieved 78% operability, the mortality being 1.5% *with the Péan-Rydygier method. The over-all mortality* among patients operated on by all members of the clinic staff, using both methods, was 1.9% during the last 3 years; there were 25 resections for perforated ulcer, 10 operations for massive hemorrhage, and 9 procedures for recurrence of ulcer. This shows that resection with gastrojejunal anastomosis can be limited, and at the same time the mortality rate can be kept down to less than 1%.

Late Results of Vagotomy in Ulcer Disease of Stomach and Duodenum. A. N. Filatov and E. A. Senchillo. Vestnik khir. 82:50-55 (April) 1959 (In Russian) [Leningrad].

The authors report on 64 patients with gastric and duodenal ulcers who were treated by vagotomy. Sixty patients were followed up. Thirty-eight of these were subjected to a subdiaphragmatic vagotomy. Nineteen patients were subjected to a vagotomy and a gastroenterostomy. Forty-seven patients were followed up for from 2½ to 10 years. The follow-up demonstrated that half of the pa*tients became worse as time went on. Best results* were noted in cases of peptic ulcer and in ulcers of the pylorus when vagotomy was combined with gastroenterostomy. The authors feel that a favorable result depends on the complete severance of all branches of the vagus and on proper evacuation of the gastric contents furnished by the gastroenterostomy. They feel that vagotomy may be recommended for gastric ulcers located high up in the fundus and for duodenal ulcers with a difficult approach. Its main indication is recurrence of ulcer disease after gastric resection.

Strangulated Obturator Hernia. U. Muraro. Riforma med. 73:332-336 (March 21) 1959 (In Italian) [Naples].

A successful operative case of strangulated obturator hernia in a 73-year-old woman is presented. The patient had had a crural hernia for 20 years without noticing any symptoms of strangulation. The author believes that in such a type of hernia the problem is more of a diagnostic nature than of an operative nature. Mild symptoms and signs, such as pain in the internal surface of the radix of the thigh, swelling noticed on examination of the rectum or the vagina, or a marked sensibility of Scarpa's triangle, are important in the diagnosis of strangulated obturator hernia. This type of hernia should be suspected especially in cases of intestinal occlusion. Intervention through the abdomen is the treatment of choice; in case this is not sufficient a femoral incision is of help. Exceptionally and only in case of a large hernia which goes to the root of the thigh should intervention begin through the thigh. The author lays emphasis on the fact that, when the diagnosis of strangulated obturator hernia is made, or when this condition is suspected, a median subumbilical laparotomy, with the patient *in an exaggerated Trendelenburg position,* affords a good approach and a clear view of the operative area.

Spontaneous Perforation of the Stomach in the Newborn: Analysis of Thirteen Cases. L. M. Linkner and C. D. Benson. Ann. Surg. 149:525-533 (April) 1959 [Philadelphia].

The authors report on 13 newborn (4 male and 9 female) infants operated on for spontaneous rupture of the stomach at the Children's Hospital of Detroit during the last 10 years. It was hoped that similarities would become apparent to establish a common etiology and a common clinical picture, which should lead to earlier correct diagnosis and, consequently, to a higher salvage of these newborn infants. The commonest symptoms were marked abdominal distention of sudden onset, vomiting, and a tympanitic abdomen. Roentgenologic examination usually revealed a large amount of free air and fluid in the peritoneal cavity or beneath the leaves of the diaphragm. The infants were then im*mediately prepared for operation. A right para*median incision or an incision through the upper midline was made. Postoperatively, continuous suction was employed until intestinal sounds were heard or stools passed. This normally occurred between 36 and 48 hours after the operation. Oral feedings by eye dropper of glucose solution every hour in 2-cc. amounts were then started and gradually increased in volume. Six of the 13 children survived.

It would seem from those surviving that a delay of more than 12 hours from perforation to surgical correction is often fatal. It is evident that survival was related directly to the promptness with which roentgenologic examination of the abdomen was made and surgical correction of the defect accomplished. Many factors have been postulated to explain the pathogenesis of this condition, but review of the site of perforation has provided no clue to the etiology. All areas of the stomach were involved with almost equal frequency, but the posterior gastric wall was involved least frequently. Pregnancy, labor, and delivery were usually normal; however, in the mothers of 2 patients toxemia was noted. Weight had little to do with the ultimate survival. An additional point that might indicate a common pathogenesis was the incidence of positive blood cultures in 3 patients. It can be postulated that septic embolization of the gastric wall might produce a local vascular insult sufficient to allow the highly acid gastric juice of the newborn *infant* to perforate through all the layers.

Subclinical or Latent Adrenal Insufficiencies. L. De Gennes, H. Bricaire and L. Moreau. Presse méd. 67:619-622 (March 28) 1959 (In French) [Paris].

Subclinical or latent adrenal insufficiency may exist even though the clinical signs suggestive of such a condition are almost indistinguishable or entirely lacking. Any unusual strain on the organism, such as an intercurrent infection or the shock of an operation, may then overtax the adrenal glands, precipitating an episode of acute insufficiency and endangering life. Investigation of the adrenal function in 10 patients in whom latent adrenal insufficiency was revealed by stress produced 2 different types of findings: (1) low static values of the steroids with a normal or slight increase in response to ACTH stimulation, and (2) normal or slightly lowered steroid values with no response to ACTH stimulation. Findings of the first type reveal a disturbance of the gland not infrequently seen in hypopituitarism, after prolonged corticotherapy, in connection with muscular inactivity in bed-fast patients, in psychasthenia, and in active visceral tuberculosis.

The adrenal inertia revealed by findings of the second type is undoubtedly due to partial but definitive impairment of the adrenal glands. Surgical procedures, especially shock-producing operations such as thoracoplasty and pneumoperitoneum, are not without danger in patients with adrenal inertia and may be followed by collapse related to the slowness of the adrenocortical response. It must be remembered that lowered urinary steroid values are not necessary for a diagnosis of adrenal insufficiency in these cases; repeated tests may show normal or only slightly lowered values, but in all cases the Thorn test fails to produce an increase. Clinical signs, such as asthenia, loss of weight, and pigmentation, often exist but may be so slight as to escape observation unless deliberately looked for; they were present in 6 of the authors' 10 patients.

Latent or subclinical adrenal insufficiencies of the kind described almost always represent incipient Addison's disease in which the glandular secretion is active enough to meet everyday needs but is quite incapable of responding to those created by a major stress. Collapse in most of the authors' patients was followed by an intensification of the Addisonian signs. Adequate hormone treatment will restore the balance in most cases and can sometimes be discontinued after the patient's recovery from the acute attack. Patients should be warned, however, that in the event of even slight shock they are to be regarded as adrenally inadequate and must be treated accordingly. The true status of the adrenal gland should also be investigated before every operation, so that prophylactic therapy can be given before, during, and after the operation when needed. This procedure, which has been adopted by some surgeons at the authors' suggestion, seems already to have borne fruit and to have brought about a reduction in postoperative mortality attributable to acute adrenal insufficiency.

Primary and "Accelerated" Early Plastic Surgery for Burns. G. Frank. Plast. & Reconstruct. Surg. 23:313-330 (April) 1959 [Baltimore].

The author describes the efforts made at the Municipal Hospital in Budapest, Hungary, to shorten the time between the burn accident and its surgical treatment. He emphasizes the importance of terminology in regard to the time elapsed between the burn accident and the treatment. He differentiates between primary and secondary operations. A primary operation should be understood to mean necrectomy and closure of the wound within 48 hours after the accident. The essential difference between primary and secondary management lies in infection and in the development of an inflammatory barrier. The term "late plastic repair" applies to the correction of scar formation and of defects. In the group of primary operations the author distinguishes between "immediate" and "delayed" primary necrectomy and grafting. Immediate primary operation is the one performed within 12 hours, and delayed primary operation is that carried out within 48 hours after the burn. In the group of secondary operations a distinction is made between "accelerated early," "retarded early," and "overdue" grafting. Accelerated early operations are the ones performed within 3 to 14 days after the accident, whereas during the ensuing 4 to 6 weeks the retarded early operations are performed.

This report is concerned with the techniques employed and the experience obtained in 43 cases of primary and 16 cases of accelerated early plastic operations for deep burns. In the conclusions the author emphasizes the following points: 1. When it is certain that a burn involving less than 2% of the body surface is deep, primary necrectomy and immediate wound closure (suture and covering by flap or graft) are indicated. 2. When an extensive burn is deep, the shock due to burn is no contraindication to operation within the first 48 hours, because tolerance can be enhanced by supporting the usual antishock measures by pharmacological hibernation by means of the lytic cocktail (in burns involving up to 10 to 15% of the body surface), or by hibernation and hypothermia (in burns more extensive than that). Surgical shock can be combatted, and meanwhile the burn shock will be over, too. 3. Grafts will take, even if the body temperature has been reduced to as low as 28 C (82.4 F), and epithelization will result. 4. Primary surgery is contraindicated when (*a*) the deep burn involves more than 30 to 40% of the body surface; (*b*) the deep burn is smaller than that but affects also the principal donor areas; (*c*) the necrotic skin cannot be removed completely (more than 5% of body surface remains necrotic); and (*d*) the trunk is deeply burned circularly, because in such cases only one aspect (anterior or posterior) of the body can be operated on. 5. When the principal donor areas are involved, primary homografting may be employed after necrectomy. 6. Only those burns should be excised in which there is no chance that epithelial regeneration may begin from the wound floor. 7. A deep burn in the center of a superficial one can be excised and grafted with success. 8. At necrectomy each part of the wound base should be examined for bleeding. 9. In extensive necrectomy the electrodermatome or Lagrot's or Humby's knives are the instruments of choice. 10. Only coagulation necrosis is suitable for accelerated early plastic surgery (necrectomy plus immediate grafting, performed within 3 to 14 days after accident). In colliquative necrosis it is advisable to be more conservative, and the rules of delayed early grafting (2 to 6 weeks) should be applied.

The Importance of Cholangiography on the Operating Table. B. A. Petrov and V. B. Antonovich. Khirurgiya 35:16-20 (no. 4) 1959 (In Russian) [Moscow].

The authors report on 150 patients with calculous disease of the gallbladder and the bile ducts who were subjected to cholangiography in the course of operation. In 44 out of 113 patients with stones in the gallbladder, the common bile duct was demonstrated to have stones in it. Jaundice was present in only 24 of the 44 patients; stones were palpated in the common bile duct in 25; and in 16 stones were demonstrated only by cholangiography.

Cancer Cells in the Blood: A Five to Nine Year Follow-up Study. H. C. Engell. Ann. Surg. 149:457-461 (April) 1959 [Philadelphia].

Blood samples from 125 patients with cancer, most of whom had intestinal carcinomas, were examined for tumor cells. Samples were drawn from the tumor area and from peripheral blood during operation for removal of the primary growth. Tumor cells were found in 34% of the grade 2 tumors, in 76% of the grade 3 tumors, and in 100% of the grade 4 tumors. The assumption that a certain number of patients, on whom radical operation had been performed and who had tumor cells in the blood, would survive a 5-year period has been confirmed by a 5-to-9-year follow-up study of the patients. Of the 125 patients, 55 were alive after 5 to 9 years. Tumor cells were found in the blood of 76 of the 125 patients. Of the 55 surviving patients, 28 had cancer cells in their blood at the time of operation. In the vast majority of these patients all tumor cells disseminated into the blood must have perished in the blood stream. This illustrates that no prognostic conclusion can be drawn from the appearance of tumor cells in the blood. The presence of such cells in the blood during surgical resection of a tumor area has been found to be related, primarily, to histological differentiation of the tumor, and, to a less degree, to local extension, while surgical trauma seems to be of little consequence in venous spread of cancer cells from colonic and rectal carcinomas. Operative trauma plays a minor role in patients with intestinal carcinomas.

The Role of Surgery in the Management of Unilateral Pleural Effusion. T. B. Ferguson and T. H. Burford. Ann. Int. Med. 50:981-998 (April) 1959 [Lancaster, Pa.].

The most common causes of persistent unilateral pleural effusion are tuberculosis, metastatic carcinoma, and heart failure, but a variety of other disease processes can give rise to such fluid collections. Determination of the etiology of such an effusion may prove difficult. One of the authors (T. H. B.) has been of the opinion that major exploratory thoracotomy should be done in patients of this type in whom the diagnosis cannot be obtained by any of the usual methods. The advantages of major thoracotomy are several. Tissue can be obtained for histological and bacteriological study with the certainty that the biopsy is representative. Decortication of the compressed lung can be done when necessary, and, if dyspnea due to rapid reaccumulation of fluid is a problem, this complication can be controlled by obliterating the pleural space with a parietal pleurectomy. If an active tuberculous process is found, the patient can then be placed on bed rest and antituberculous therapy. If a malignant lesion is present, palliation can be achieved by relieving the dyspnea caused by fluid accumulation.

The authors present observations on 21 patients with persistent unilateral pleural effusion, whom they observed during the last 7 years. The average age of the patients was 51 years, and the group included 16 males and 5 females. Fluid accumulation had persisted for an average of 3½ months. The effusion contained gross blood in 7 of the 21 patients. After the usual diagnostic methods had failed, all the patients were subjected to elective exploratory thoracotomy. Only 3 patients proved to have malignant disease at operation. Of the remaining 18 patients, 6 had tuberculous pleuritis, and 12 had nonspecific inflammation of the pleura. The presence of blood in the effusion was of no help in determining whether the causative process was neoplastic or inflammatory. Of the 7 patients with a bloody effusion, 1 had cancer, and 6 had inflammatory disease. All the patients derived therapeutic benefit from operation. Restoration of lung function was accomplished by decortication when a constricting membrane was present. Fluid reaccumulation was permanently abolished by performing a total parietal pleurectomy. Sixteen of the 21 patients are clinically well more than 3 years after operation, including 6 patients with active tuberculosis of the pleura. The authors conclude that exploratory thoracotomy with pleural biopsy, decortication, and parietal pleurectomy should become an integral part of the management of every patient who has a persistent undiagnosed unilateral effusion.

Coarctatio Aortae Abdominalis. A. L. D'Abreu, C. G. Rob and J. F. Vollmar. Arch. klin. Chir. 290: 521-546 (no. 6) 1959 (In German) [Berlin].

The authors report on a 58-year-old woman and on a 40-year-old man with coarctation of the abdominal aorta, who were operated on in the surgical departments of St. Mary's Hospital in London and the Queen Elizabeth Hospital in Birmingham, England, during 1957-1958. The woman had a segmental coarctation of the abdominal aorta with localization below the origin of the renal arteries. Signs of intermittent claudication predominated in the clinical picture. The onset of symptoms occurred when the patient was 40 years old. For 6 years an erroneous diagnosis of multiple sclerosis was maintained, and later an erroneous diagnosis of thrombosis of the aorta was made. High lumbar aortography revealed coarctation of the aorta. Considerable improvement of the blood circulation in the lower portion of the body resulted from a splenoaortic bypass operation with insertion of a homologous arterial graft. Coarctation of an unusually long segment of the abdominal aorta of the "deep"-thoracicoabdominal type was found in the man. Hypertension of 15 years' duration, representing the clinical guiding symptom, had been treated unsuccessfully with drugs and by thoracolumbar sympathectomy. Symptoms of intermittent claudication were present for the last 5 years. Resection of a constricted area of about 20 cm. in length could not be considered because of its location. An almost complete cure of the deficient circulation of the caudal portion of the body and of the hyptertension of the upper portion of the body resulted from an aortoaortic bypass. Twenty-two additional cases of coarctation of the abdominal aorta in 11 men and 11 women, of the average age of 34.2 years at the time the clinical diagnosis was made, were collected from the literature.

The following types of coarctation of the abdominal aorta may be distinguished from the morphologic viewpoint and from that of localization: (1) segmental and hypoplastic type and (2) infrarenal, intrarenal, and suprarenal type. The close topographic relationship of most of the forms of coarctation with the renal arteries may result not too rarely in a partial or complete occlusion of these arteries. The clinical picture, as a rule, is predominated by the signs of deficient arterial circulation of the lower portion of the body (intermittent claudication of the legs), and less frequently by hypertension of the upper half of the body or by signs of an overload placed on the heart. The diagnosis is supported primarily by the demonstration of a deep (thoracicoabdominal) collateral circulation (pulsating vessels at the borderline of the thorax and abdomen, bone erosion at the lowest ribs, vascular sounds in the course of the abdominal aorta and at the back). The diagnosis of the vascular narrowing can be established by aortography. Thrombosis of the aorta and essential or renal hypertension are the most frequently made erroneous diagnoses. Direct operative removal of the coarctation is indicated only in patients with short constricted segments, which are cranial or caudal of the "critical" zone of origin of the large visceral arteries. A bypass operation is to be preferred for coarctation in the "critical" zone. Sympathectomy should be limited to cases of the hypoplastic type; it is a purely palliative measure, and its results in patients with coarctation of the abdominal aorta were disappointing.

Disability Following Gastric Surgery for Benign Disease, as Observed by the Internist. E. D. Palmer. Ann. Int. Med. 50:928-935 (April) 1959 [Lancaster, Pa.].

This report deals with 157 patients who had had a stomach operation for benign disease, and who subsequently either consulted a medical outpatient clinic or were referred to a medical hospital ward. In 83 instances the operation had been a Billroth 2 subtotal gastrectomy; in 40, vagotomy and gastroenterostomy; in 29, simple gastroenterostomy; and in 5, total gastrectomy. The operations had been done by many surgeons in many hospitals. No effort was made to evaluate the effectiveness of different operative procedures. All the patients were hospitalized for at least part of the study. In addition to the usual clinical evaluation, they were studied by periodic upper gastrointestinal roentgenography and gastroscopy. The patients who had undergone total gastrectomy were examined by esophagoscopy and by jejunoscopy. Thirty-two of the other patients were also studied esophagoscopically.

In 56% of the patients, an organic postoperative complication was found, with or without additional functional problems, and in many of them a new set of symptoms had replaced the preoperative ones, often a long period after surgery. In the other 44%, the symptoms were judged to have a nonorganic basis. Except for the 29 patients who had been treated by simple gastroenterostomy, and in 23 of whom organic causes were found, the causes of the disability were rather evenly divided between the organic and the nonorganic. Many of the patients in whom a specific organic diagnosis was possible also had nonorganic problems, both physiological and emotional. Forty-three of the patients came to medical attention because of upper gastrointestinal hemorrhage. These included all the patients in whom erosive esophagitis and gastritis were diagnosed during active bleeding by esophagogastroscopy. Anastomotic ulcer, gastric ulcer at a distance from the stoma, and active duodenal ulcer accounted for the hemorrhage in most of the others.

No cause was found in 7 patients who could not be examined until bleeding had stopped for some time. One of the more interesting causes of bleeding was adenoma of the jejunum, arising just below the stoma; this was discovered in 3 patients who had had subtotal gastrectomy. They were treated by local excision with revision of the stoma. Gastric carcinoma eventually developed in 2 patients who had been operated on for duodenal ulcer. In one of them symptoms leading to the discovery of cancer began 26 years after subtotal gastrectomy. The other patient had had a vagotomy and gastroenterostomy 8 years previously.

The most significant feature of the group without organic disease was that all but 4 of the 69 patients had been operated on because of duodenal ulcer and that only 3 of these had had an organic ulcer complication. Complaints in this group included the dumping syndrome, or anorexia, nausea, vomiting, weight loss, diarrhea, and fainting in various combinations. The most difficult group was composed of 30 patients who just had not felt well since operation. They never seemed sure of how they had changed. They did not feel the way they had before, but neither did they feel the way they thought they should now. Some seemed to have undergone an emotional change. They seemed to be abnormally dependent on both medical and family figures in a compulsive sort of way, sometimes but not regularly using the fact of their operation to manipulate their surroundings. Additional surgery was carried out in 48 of the 157 patients, and 2 were subjected to esophageal dilatation. The others, including those with nonorganic lesions, were treated by conservative medical measures and by interview therapy.

Modification of Blood Clotting Abnormalities by Splenectomy in Chronic Idiopathic Thrombocytopenia. G. Winckelmann. Ztschr. klin. Med. 155:536-543 (no. 6) 1959 (In German) [Berlin].

The author studied the influence of splenectomy on the processes involved in blood coagulation in 10 patients (9 women and 1 man) with idiopathic thrombocytopenic purpura. Particular attention was given to the maximal retractility of the clot in the graph illustrating the clotting process, the consumption of prothrombin, and the thrombocyte count after splenectomy. After a successful splenectomy there occurred within 6 hours, despite only a minor increase in thrombocytes, a noticeable increase in the density of the clot and a growing consumption of prothrombin, that is, the platelet function was increased. The prompt postoperative onset of the emergence of functionally adequate thrombocytes into the circulating blood was attributed to the abolishment of a splenogenic inhibitory effect on the bone marrow. In addition, the favorable hemostatic effect of splenectomy even in the presence of a low thrombocyte count indicated a favorable modification of the vascular factor. In 6 patients the splenectomy achieved complete improvement of their defect, with normalization of the thrombocyte count, of the changed coagulation process, as well as permanent improvement in the clinical symptoms. In one patient the bleeding tendency disappeared coincidentally with normalization of the capillary resistance and of the bleeding time, whereas the thrombocyte count and the disturbances in coagulation remained unchanged. In the remaining 3 patients splenectomy was followed by only a slight improvement in the hemorrhagic diathesis.

NEUROLOGY & PSYCHIATRY

Twenty-Six Cases of Atherosclerotic Obstruction of the Sylvian Artery. T. Alajouanine, P. Castaigne, F. Lhermitte and others. Semaine hôp. Paris 35: 1145-1149 (March 28) 1959 (In French) [Paris].

Obstructive atherosclerosis of the sylvian (middle cerebral) artery is one of the most frequent and recognized causes of softening in the region of the sylvian artery, but the arterial lesions and their connection with the cerebral necrosis are by no means well known. Special interest, therefore, attaches to the findings in 26 cases in which atherosclerotic obstruction of the sylvian artery was demonstrated by arteriography, because they make it possible to relate the clinical picture to the site of the obstruction. The anatomic and clinical correlations thus established help to clarify the physiopathology of the circulatory disturbances.

Classification of the atherosclerotic obstructions according to their position in the arterial trunk revealed 3 principal groups: (1) those occurring at the origin, which deprive the whole of the artery. including its perforators, of normal blood supply; (2) those at the threshold of the insula, where the arteries of the cortical and subcortical territory originate: among these, only the anterior temporal, already detached from the trunk of the sylvian, can escape the consequences of the obstruction; and (3) those at the origin of the trunk of the ascending arteries, on which the irrigation of the frontal and parietal convolutions largely depends.

The onset of the symptoms was almost always abrupt (23 cases), but loss of consciousness was comparatively rare (4 cases). A rapidly progressive development, within a few hours, of major disorders was much less common, having been observed only twice. A most unusual onset, finally, was seen in 2 patients in whom the disturbances increased little by little over a period of months. Premonitory signs, reported in nearly half the cases, consisted of paresis in 2; transient but always recurring paresthesias, lasting for minutes or hours, in 5; critical sensory or motor phenomena in 2; and headache in 3. These signs preceded the stroke by only a few days in 2 cases, but more often they revealed the development of the arterial process for months or even years before the onset of hemiplegia.

Hemiplegia and aphasia are the characteristic disturbances of cerebral softening due to obstruction of the sylvian artery, but they vary greatly in intensity. Different clinical pictures may, therefore, be produced by obstructions in one site, and, at the same time, the pictures produced by obstructions in several different sites may be identical. It follows, then, that some intermediate factor capable of explaining the variability of the circulatory deficit and its regular predominance in the same regions of the brain must intervene between the obstruction of the artery and the development of ischemia. This factor is to be found in the variability of the collateral circulation, which is supplied by meningeal anastomoses differing widely in their effectiveness and in the conditions under which they are brought into play. The insufficiency of the meningeal anastomotic networks also explains why cerebral softening due to obstruction of the sylvian artery is much more stereotyped in its expression and also, on the whole, much more serious than that caused by obstruction of the internal carotid artery, the consequences of which depend largely on the ability of the circle of Willis to provide collateral circulation.

Arteriographic studies in 86 patients in whom cerebral vascular accidents had occurred showed that one-third were due to obstruction of the sylvian artery, one-third to obstruction of the internal carotid artery, and one-third to undetermined causes. Arterial bifurcations are known to be an elective site for atherosclerotic lesions, and it is interesting in this connection to note the close anatomic similarity between the internal carotid and the sylvian arteries at their points of origin. Both arteries continue in the direction of the vessels from which they take their origin, and both receive the greater share of the blood carried by the parent vessel. The external carotid and the anterior cerebral arteries, on the other hand, receive the smaller share and branch off at a definite angle. The similarity of the morphologic and hemodynamic conditions at these 2 points of bifurcation in the arterial system inevitably invites comparison with the similarity of the lesions to which they are subject.

Bilateral Obstruction of the Internal Carotid. T. Alajouanine, P. Castaigne, F. Lhermitte and others. Semaine hôp. Paris 35:1149-1160 (March 28) 1959 (In French) [Paris].

The clinical and anatomic findings obtained in studying 5 patients with bilateral obstruction of the internal carotid arteries clearly revealed the importance of the collateral circulation in determining the effect of such an obstruction on the cerebral circulation. Complete suppression of the arterial supply of the internal carotid does not necessarily lead to necrosis of the whole of the parenchyma supplied by the middle and anterior cerebral arteries. Arteriographic studies made by the authors in 3 of their 5 patients show that partial reestablishment of the circulation takes place by way of the ophthalmic artery, the posterior communicating arteries, and perhaps the superficial anastomoses. Intermediate conditions of every kind are to be found between the cases in which the inadequacy of the collaterals makes bilateral carotid obstruction a fatal accident and those in which the collateral vessels are able to satisfy the requirements of the cerebral circulation.

The manifestations that characterize bilateral, as well as all other forms of cerebral arterial obstruction are linked to many other imperfectly understood factors. A few points, however, may be noted. 1. Collaterals adapt themselves to the new conditions created by the obstruction of a vessel, and the more slowly the obstruction develops, the better the adaptation. This fact was illustrated by the severity and abrupt onset of 2 cerebral accidents due to emboli in one of the patients, who had complex heart disease, as compared with the long history of transient disturbances presented by 2 other patients who had atherosclerotic thromboses, one of whom is leading a normal life in spite of the bilateral obstruction, while the other lived for a fairly long time (2 years and 3 months), although he had an occlusion of the vertebral artery as well as bilateral obstruction of the internal carotid arteries. 2. All parts of the brain are not equally exposed to the danger of ischemia by obstruction of the internal carotid arteries, but too many variables are involved to permit the formulation of a general rule. It was noteworthy, however, that in the 3 cases in which an autopsy was performed, the region of the sylvian artery was the site of important lesions, while the regions of the anterior and posterior cerebral arteries were only slightly or not at all affected. This is readily understandable in the case of the posterior cerebral artery but not so easy to explain in the case of the anterior cerebral artery. This unequal distribution of the lesions results from the anatomic and hemodynamic conditions governing the new organization of the circulation. Some of these are connected with the fact that the flow in the sylvian artery is greater than the flow in the anterior cerebral, so that, with a lessened arterial supply, the territory supplied by the latter vessel will be the one more easily irrigated; others depend on the capacities of the 3 components of the anastomotic network. A contrast medium injected into the ophthalmic artery after bilateral obstruction of the internal carotids, for example, enters the anterior cerebral in preference to the sylvian artery, whereas after unilateral obstruction the anterior cerebral is regularly injected by way of the contralateral carotid artery. The vast territory of the sylvian artery may be revascularized by the posterior communicating artery, but the fact that this vessel is often reduced in caliber readily explains its inadequacy as a collateral. The superficial networks participate, of course, in the work of revascularization, but their capacity is limited. Circulatory inequalities leading to varying degrees of necrosis are also to be found within the sylvian region itself. The clinical characteristics and course of the manifestations of bilateral obstruction of the internal carotid arteries thus depend on the intensity, duration, and site of the ischemia to which it gives rise.

The Cerebral Arteritis of Bacterial Endocarditis: Its Late Complications. T. Alajouanine, P. Castaigne, F. Lhermitte and J. Cambier. Semaine hôp. Paris 35:1160-1165 (March 28) 1959 (In French) [Paris].

Cerebral accidents in patients with bacterial endocarditis may occur at any time during the course of the disease or months or even years later. They are almost always the result of an arterial process ending in cerebral softening or a cerebral or meningeal hemorrhage. Hemiplegia is the commonest clinical expression of such an accident. Clinical, arteriographic, and biological data obtained in 3 personal cases serve to define the nature of the arterial lesion, the mechanism of the accidents it engenders, and its future after the subsidence of the infection. The first patient was a 33-year-old man in whom hemiplegia on the right side, accompanied by aphasia, appeared at the beginning of an attack of bacterial endocarditis due to a streptococcus of the viridans group. The cardiac infection responded rapidly to treatment with antibiotics, but the hemiplegia and aphasia showed little improvement. Two arteriograms of the left carotid artery, one taken during the initial phase of the hemiplegia and one 3 months later, revealed an aneurysm at the end of the left internal carotid and obstruction of this segment of the artery. A cerebrospinal fluid specimen obtained on the third day of the illness contained 2,500 cells per cubic centimeter, 95% of which were polymorphonuclear leukocytes.

The second patient was a 20-year-old youth who was suddenly affected by a predominantly brachiofacial hemiplegia on the left side 5 months after the clinical and biological cure of an attack of bacterial endocarditis unaccompanied by neurological signs of any kind. Arteriography revealed a narrowing of the last 2 cm. of the carotid, with an obstruction blocking the openings of the middle and anterior cerebral arteries and, finally, a calcification situated at the level of the obstruction. The cerebrospinal fluid contained 700 cells (80% lymphocytes) per cubic centimeter. No signs were found to indicate a resumption of the endocarditic process.

The third patient was a 47-year-old man with aortic insufficiency of rheumatic origin, who recovered completely from an attack of bacterial endocarditis after having been treated with penicillin for one month. Two years later a left-sided hemiplegia appeared abruptly during exposure to severe cold weather. Serious sequelae developed, and 18 months later the patient was hospitalized at the Clinique des Maladies du Système Nerveux, Paris, so that he could be given reeducative therapy for motor and speech disturbances. Arteriography of the right carotid revealed complete obstruction at the origin of the sylvian artery and a small aneurysm at the bifurcation of the internal carotid.

The cerebral accident in each of these 3 cases was undeniably softening produced by an obstruction at the junction of the carotid and sylvian arteries. The circumstances in which it became manifest, however, and the findings on arteriographic examination of the patients contribute to an understanding of the arteritis accompanying bacterial endocarditis. The arteriographic pictures leave no doubt that the lesion responsible for the cerebral disturbances consists of a focal injury to the arterial wall and the changes occasioned thereby. The processes illustrated—narrowing of the lumen of the carotid, arterial obstruction, aneurysmal dilatation, intraparietal calcification—evoke those already familiar in the arteries of the limbs and other territories of the body—inflammatory infiltration and alteration of the vessel wall ending either in obstruction or aneurysmal dilatation. The interval between the cure of the endocarditis and the occurrence of the cerebral accident in the last 2 patients (5 months and 2 years, respectively) seems to show that inapparent lesions may become established in the carotid and sylvian arteries during the course of bacterial endocarditis and that they may continue to develop independently after the endocarditis has been cured. The inflammatory reaction in the cerebrospinal fluid of the first 2 patients suggests either the latent development or the reawakening of arteritic foci. The location of the arterial lesions at the bifurcation of the internal carotid can perhaps be explained by the hemodynamic conditions found in that region. These conditions are known to be a determining factor in the localization of atheroma and the elective localization of sylvian thromboses. It may be noted that aneurysms of the cerebral arterioles can only reveal themselves by rupture, whereas accidents of ischemic necrosis, such as those reported by the authors, imply the obstruction of a major arterial trunk. This may explain the heretofore classic distinction made between aneurysms, which were attributed to arteritis, and obstructions, for which embolism was considered responsible.

Cerebral Atrophy Associated with Boxing. K. T. Neubuerger, D. W. Sinton and J. Denst. A. M. A. Arch. Neurol. & Psychiat. 81:403-408 (April) 1959 [Chicago].

While neuropsychiatric complications in boxers are well known, few reports have been published on the cerebral pathological aspects, particularly with regard to the late sequelae. The authors made studies on 2 patients with dementia pugilistica. Cerebral cortical biopsy in one patient revealed mild neuronal degeneration and definite plasmatic gliosis in the lower cortex. The brain of the other patient was severely atrophic, presenting a picture which grossly and microscopically resembled presenile brain atrophy (Pick's disease). As in other cases, the disease became manifest some years after cessation of professional boxing. The authors compare observations on their patients with descriptions of the pathological aspect of dementia pugilistica given by German investigators, who felt that the term "dementia pugilistica" should be reserved for cases of chronic progressive disorders developing after a symptom-free interval, and that neurological disturbances arising in immediate connection with head injuries should be called "traumatic encephalopathy of boxers." While the 2 cases presented have failed to reveal argentophilic changes, undoubtedly they belong in the group of senile and presenile cerebral involutions (senile brain atrophy, Pick's and Alzheimer's diseases). The mechanism of involution is understood best with the help of von Braunmühl's theory on the process of aging of the colloids of the brain. This process is characterized by diminution in the degree of dispersity of the colloids and by the separation of the medium of dispersion into 2 phases of different colloidal content, one of which consists of concentrated colloid with little water, and the other of a thin, watery medium with little colloid.

The authors feel that the pathogenesis of the traumatic lesions in their cases may be explained in accordance with the views of Brandenburg and Hallervorden and of Grahmann and Ule, which were predicated on von Braunmühl's theory. These authors believed that the cerebral alterations are thixotropic in origin. [Thixotropy, a term used in colloid chemistry, is the disturbance of the gel-sol equilibrium caused by shaking, stirring, ultrasound, or other mechanical factors.] Concussion produces a change in the colloid medium of the cerebral tissue, according to Hallervorden. Boxers may be subject to repeated concussions that, although often subliminal, may be assumed to incur sequelae. This supposition is substantiated by electroencephalographic abnormalities in boxers. It is suggested that, in the absence of focal lesions, the pathogenesis is explained best on the basis of a thixotropic process, leading to premature aging of the brain. These cases emphasize the complexity of the pathological processes and the desirability of careful examination of the brains of former boxers.

PEDIATRICS

Cord-Blood Findings in ABO Haemolytic Disease. G. H. Tovey, E. M. Gillespie, J. Guy and others. Lancet 1:860-863 (April 25) 1959 [London].

The authors studied samples of cord blood collected from 575 babies at Southmead Hospital in Bristol, England, whose mothers were known to be group O, since hemolytic disease caused by ABO incompatibility in the newborn infant is most frequent in babies born of group O mothers. In 393 of the 575 infants the baby's blood group was O, i. e., "compatible"; in the remaining 182 infants it was A or B, i. e., "incompatible." Of the 393 blood group O infants, 23 (6%) were deeply jaundiced, 113 (29%) were slightly jaundiced, and 257 (65%) were not jaundiced. Of the 182 blood group A or B infants, 18 (12%) were deeply jaundiced, 54 (28%) were slightly jaundiced, and 110 (60%) were not jaundiced. The incidence of slight jaundice thus was not significantly different in compatible and incompatible infants. By contrast, deep jaundice was more frequent in the ABO incompatible infants. The hemoglobin level in the cord blood samples obtained from compatible infants was neither in range nor in mean significantly different from the cord blood hemoglobin level of the incompatible babies. While the mean of the serum bilirubin level in the cord blood samples obtained from compatible infants did not differ significantly from that in the incompatible infants, there was a difference in range (0.6 to 3.5 mg. per 100 cc. in the compatible infants, and 0.5 to 4.7 mg. per 100 cc. in the incompatible infants).

Hemoglobin and serum bilirubin levels in the cord blood samples did not correlate well with the clinical progress of the infant, and a cord hemoglobin level below 16.6 Gm. per 100 cc. or a bilirubin level above 3 mg. per 100 cc. is not necessarily an indication for an exchange transfusion in this condition. The modified direct antiglobulin and sodium chloride solution fragility tests, proposed by Rosenfield, and the reticulocyte counts did not facilitate the diagnosis. Deep jaundice appeared earlier and more frequently after ABO heterospecific pregnancy than homospecific pregnancy. The highest over-all incidence of neonatal jaundice was in babies immature by age of gestation, and it was not influenced by ABO incompatibility. The clinical assessment and cord blood examination thus showed the need for caution in the interpretation of cord blood findings in infants thought likely to show ABO hemolytic disease. Exchange transfusion for ABO hemolytic disease is not necessary unless the serum bilirubin rises to dangerous levels. This can be determined only by close observation and repeated measurement of the serum bilirubin level.

Studies on the Occurrence of Bacteremia in Rheumatic Fever. C. J. Marienfeld, G. Scheff, E. Hackett and D. Jones. J. Chron. Dis. 9:334-352 (April) 1959 [St. Louis].

This study which is based on findings obtained from cultures of blood in 185 patients with rheumatic fever, and in a comparable series of 100 nonrheumatic contratest patients, deals with the possibility that an enterococcus-like organism may serve to continue the rheumatic fever instigated by group A streptococci. The ages of the patients ranged from 5 to 15 years. Three hundred eighty-five blood cultures were obtained from the 185 patients with rheumatic fever, and 124 blood cultures were drawn from the untreated 100 patients in the contratest group. Fifty of the 100 patients had afebrile illnesses, and 50 had febrile illnesses of various types.

Of those patients in both groups who had received no treatment, the results on the occurrence of bacteremia were as follows: Diplostreptococcus organisms were found in 66% of the 36 patients with rheumatic fever in the acute stage, in 22% of the 9 patients in the convalescent stage, and in 10% of the 53 patients in the inactive stage. The percentage of positive cultures, including staphylococcic contaminants, was 14% in the febrile contratest patients and 12% in the afebrile contratest patients. The high percentage of positive cultures in the rheumatic patients appeared to be related to both the acuteness of the disease and the absence of antibiotic or salicylate medication. The organisms obtained have been identified as being most closely related to the enterococcus group of streptococci, most of them belonging to group D. It is suggested that the presence of these organisms in the blood stream may be an indication of their importance in the pathogenesis of the rheumatic process initiated by group A beta-hemolytic streptococci.

Vaccination Against Whooping Cough: The Final Report to the Whooping-Cough Immunization Committee of the Medical Research Council and to the Medical Officers of Health for Battersea and Wandsworth, Bradford, Liverpool, and Newcastle. S. Bedson, P. Armitage, W. C. Cockburn and others. Brit. M. J. 1:994-1000 (April 18) 1959 [London].

The authors report the results of field trials with 7 different pertussis vaccines made in various parts of England; in these trials 13,029 children attending local authority clinics were inoculated and followed up for 2 or 3 years. The results of the trials clearly showed that it was possible to produce by vaccination a high degree of protection against whooping cough, as shown by the substantial reduction in the attack rate among home contacts, and, in those cases in which vaccination failed to give complete protection, it was possible to reduce the severity and duration of the disease. The different vaccines employed varied in their protective action. Of 2 vaccines prepared in liquid medium, one was not significantly different in its protective properties from the vaccine prepared on solid medium; the other was significantly different, but the reason for this was not clear and the number of observations was small. The protective antigen extracted from Hemophilus pertussis by Pillemer and co-workers in 1954 was, in the concentration used, more effective in its protective action than a whole bacterial vaccine, but caused more reactions. The protective action induced by a pertussis vaccine mixed with diphtheria toxoid (F. T.) was similar to that induced by the same pertussis vaccine alone.

The results of serologic tests in the trial of the mixed vaccine showed that the diphtheria antitoxin response was slightly less in a group of children receiving 3 doses of the mixed vaccine than in a similar but slightly older group of children who received 2 doses of a purified diphtheria toxoid precipitated by aluminum phosphate (PTAP). Serologic tests were also made of the ability of the pertussis vaccines to produce specific agglutinin in mice and in children. The results, together with those previously obtained, were compared with the degree of protection afforded in children. A general correlation was obtained with whole bacterial vaccines between protection and agglutinin production, but not with Pillemer's antigenic fraction. Thus, agglutinin production cannot always be taken as evidence of protective activity.

The 7 vaccines were assayed for their protective potency by the intracerebral mouse protection test, and their relative potencies were compared, together with those of the 18 vaccines used in previous studies. A comparison between the results of the field trials and the laboratory tests of all 25 vaccines showed a high degree of correlation between the potency of the vaccines in protecting mice against intracerebral infection and their ability to protect children against pertussis. These findings confirm the previous observations and strengthen the conclusion that only those pertussis vaccines which have been shown, by the intracerebral mouse protection test, to have an adequate potency in relation to the British standard pertussis vaccine should be used in prophylaxis against whooping cough.

Complications of Influenza and Its Relationships with Pulmonary Tuberculosis in Children. C. Caione, I. Santillo and V. Gammarrota. Ann. Ist. Carlo Forlanini 18:385-400 (no. 4) 1958 (In Italian) [Rome].

All 52 children, between the ages of 1½ and 13 years, who were being treated for pulmonary tuberculosis on the pediatric ward of the Carlo Forlanini Institute in Rome, contracted influenza during the 1957 epidemic of Asian (type A) influenza. Four of these children also presented bronchiectasis and a polycystic lung. Some children suffered from mild diffused bronchitis with asthma. In 6 children bronchopneumonia developed 2 or 3 days after the influenza and, in general, affected the base of the lungs. This complication was favored by posttubercular bronchiectatic alterations in 3 children and by congenital malformations in 1. The inflammation disappeared within 5 or 6 days, with the exception of one child in whom it lasted longer. Three children had slight or temporary attacks of fever as a result of subacute tonsillitis, and 2 had purulent otitis media. Peripheral circulatory insufficiency was observed in 12 children; during convalescence these children suffered collapse, combined with nausea, perspiration, slow pulse, and arterial hypotension. Examination after recovery from influenza showed slight myocardial involvement in 7 children, but this involvement was no longer present after 2 months.

Some hemorrhage with increased vasal fragility was observed in 10 children. Several children during the first 2 days of the influenza showed neurological involvement. A delayed energizing effect of the illness was noticed in those whose organic resistance diminished and an unfavorable evolution of the tuberculosis followed. Erythrocyte sedimentation tests gave high values in all the children; after 2 months these values had returned to preinfluenza levels in 42 children, had increased in 6, and had improved in 4. All the children lost weight during the illness, but afterward most of them regained some weight; two, however, remained stationary, and one lost more weight. Roentgenologic examinations made 2 or 3 months after the influenza showed that in all but 3 children the course of the tuberculosis had not deteriorated. Tuberculin reaction showed hyperergia in one of these 3 children and diminution of skin reactivity in another.

Short-Term Hormone Therapy: Its Effect in Active Rheumatic Carditis of Varying Duration. M. G. Wilson and Wan Ngo Lim. New England J. Med. 260:802-807 (April 16) 1959 [Boston].

In a previous report of the effect of short-term hormone therapy in 55 patient attacks of active carditis of 3 to 21 days' duration, the authors had demonstrated that in the majority of the patients early adequate hormone therapy for an average period of 7 days resulted in no overt residual cardiac damage. This study is concerned with the effect of short-term steroid therapy in 53 additional patient attacks. The 53 attacks occurred in 47 children, ranging from 3 to 19 years of age, who were observed on the pavilions of the New York Hospital. They received antibiotics during their stay in hospital. The steroids used included hydrocortisone, prednisone, prednisolone, and methylprednisolone. Therapy was given every 6 hours for an average period of 7 days, and was terminated abruptly. Patients were observed for an additional week, with modified bed rest. The amount of steroids given daily was guided by the circulating-eosinophil response each morning, 4 hours after the last medication. Five patients required a second course of 7 days of hormone therapy. The duration of carditis before therapy was 21 days or less in 36 patients, and 4 to 10 days in 30 of these. In 17 patients the duration of carditis before therapy ranged from 22 days to 4 months.

Among the 55 patient attacks of carditis in the earlier study and 36 in the present report, when the duration was less than 3 weeks and in the majority less than 10 days, effective short-term therapy resulted in termination rather than suppression of the clinical signs and symptoms of carditis without overt residual cardiac damage. Patients were ambulatory 2 or 3 weeks from the onset of therapy, and their cardiac status, as noted at the end of therapy, was maintained for a follow-up period of 3 months to 8 years. These observations suggest that long-term hormone therapy is probably not required. Of 17 patients in initial and recurrent attacks of carditis of 22 days' to 4 months' duration, progressive symptoms of carditis were terminated without further increase of residual cardiac damage beyond that present at the onset of therapy.

The gross and histological findings in 38 patients with carditis of variable duration, who received symptomatic therapy between 1934 and 1938, revealed that predominantly reversible lesions characterized the findings among children with carditis of short duration, in contrast to the minimal reversible lesions and extensive irreversible damage sustained when the carditis was of longer duration. In 24 initial attacks of short duration, in which new systolic and diastolic murmurs were present, the valve leaflets were delicate. The heart weight was 1 or 2 times the expected weight when the duration was less than one month, and 3 or 4 times when the duration was longer. There was a close correlation between radioscopic estimate of heart size and the heart weight. In active carditis short-term hormone therapy will terminate the inflammatory process irrespective of its duration. Only with early adequate hormone therapy can residual cardiac damage be expected to be prevented or minimized.

An Inborn Error of Lipid Metabolism. J. A. Bigler, R. F. Mais, R. M. Dowben and D. Yi-Yung Hsia. Pediatrics 23:644-661 (April) 1959 [Springfield, Ill.].

The authors report a new clinical syndrome characterized by hepatomegaly, retardation of physical and mental growth, and disturbance of lipids in the plasma. The abnormalities were present in 2 siblings born of parents who were second cousins. None of the other 6 siblings was affected. The disturbance, characterized by an increase in the concentrations of triglycerides and phospholipids in the plasma, has been described in detail biochemically. The concentrations of cholesterols were not greatly increased, although there was an alteration in the ratio of the concentration of cholesterol esters to that of total cholesterol. By means of paper and agar-gel electrophoresis, the authors found the disturbance to involve primarily an increase in the concentration of alpha$_2$-lipoproteins. Using zone electrophoresis on starch medium, they showed that there was an increase in the concentrations of phospholipids and triglycerides in alpha$_2$-lipoproteins and of triglycerides in alpha$_1$-lipoproteins. Starch electrophoresis revealed the disturbance to be distinct from that of idiopathic hyperlipemia or primary hypercholesteremia. Ultracentrifugal analysis showed an increase in each of the fractions, but this was most marked in the serum lipoprotein fraction with S_f 20-400. This fits well with the concept that this represents primarily a disturbance in the concentrations of triglycerides and phospholipids, and very little change in cholesterols. This is also compatible with an increase in the concentration of alpha$_2$-lipoproteins.

The presence of a similar abnormality of lipids in 2 siblings of a consanguineous mating provides strong suggestive evidence that this defect is hereditary in origin; most probably it is transmitted by a rare autosomal recessive gene. Since the nature of this lipid abnormality is quite different from that of idiopathic hyperlipemia and primary hypercholesteremia, it should be classified as a new third "inborn error of lipid metabolism."

Carotid Artery Occlusion in Childhood. H. Stevens. Pediatrics 23:699-709 (April) 1959 [Springfield, Ill.].

The inclusive term "infantile hemiplegia" usually implies cerebral venous thrombosis. However, cerebral arterial occlusion may cause hemiplegia in childhood and infancy. The author reports 3 children, aged 1, 5½, and 13 years, in whom the internal carotid artery was the site of the occlusion. The initial onset in the 3 children occurred spontaneously without a history of trauma. In 2 patients the symptom was an ipsilateral severe headache; the third patient was unable to move the right arm or leg on awakening in the morning. The clinical manifestations and course were identical with those of carotid artery occlusion in adults. The diagnosis can be made sometimes on the basis of clinical data alone. Diagnosis can be suspected from the history of a "stuttering" pattern of recurrent, stereotyped, focal neurological involvement, appearing hours to months before the hemiplegia appears. Mental symptoms and papilledema are common. A valuable diagnostic sign is a transient or permanent Horner's syndrome ipsilateral to the carotid artery thrombosis. Palpation of the carotid arteries, a useful but too often neglected technique, may provide the decisive sign, justifying the diagnosis and justifying the use of carotid arteriography.

The cause of spontaneous nontraumatic carotid artery occlusion in childhood remains a mystery. Only a few instances have been reported. Disseminated vascular degeneration may involve the carotid artery in some instances, or an isolated atheromatous plaque may be responsible. Elaborate investigations, including multiple laboratory tests, should be made to establish a primary cause for the occlusion, such as an associated endocardial fibroelastosis which was detected in 1 of the 3 children. This child died, while the other 2 recovered completely.

It is suggested that therapy be directed toward preventing complete thrombosis, or the extension of the thrombosis, in a presumably isolated lesion which is probably due to localized arteriosclerosis. This reasoning further warrants conservative medical treatment as against surgical treatment of acute spontaneous carotid artery thrombosis in children. In instances of arterial spasm or other nonthrombotic obstruction, prophylactic use of anticoagulants should be considered, since thrombosis is likely to follow if spasm is sustained.

Lymphopneumatosis Cystoides Intestinalis With Eosinophilia in the Infant. J. Gagnon and M. Rheault. Pediatrics 23:710-717 (April) 1959 [Springfield, Ill.].

Lymphopneumatosis cystoides intestinalis, also known as intestinal emphysema or abdominal gas cysts, is a relatively rare pathological entity in the infant. The diagnosis of this condition is usually made at autopsy or in the course of an operation. However, crepitations are elicited by deep palpation of the abdomen, and tympanism by percussion. A roentgenogram of the abdomen occasionally will show double-contoured intestinal loops and a generalized reticular image of the abdomen. The presence of pneumoperitoneum and of trapped gas helps in clinching the diagnosis. The gas cysts are sometimes visualized by proctoscopic examination. A history of gastrointestinal distress, especially diarrhea, repeated infections, and the clinical picture of general debility are the usual clinical findings in pneumatosis cystoides intestinalis in the child. The complications which appear to be most frequently associated with the disease are intestinal obstruction and pneumoperitoneum.

The authors studied pneumatosis cystoides intestinalis in 5 infants, ranging in age from 15 days to 5 months; autopsies were performed on these patients from 2½ to 18 hours after death. The disease had a duration of from 1 week to 2 months. All the patients presented nonspecific lesions typical of the stage of "exhaustion" of the "adaptation syndrome." The lungs of all 5 patients contained evidence of acute pyogenic inflammation in the form of bronchopneumonia, abscess formation, or diffuse parenchymal infiltration. In all the infants bacteria were found to be present in the intestinal lumen and in some of them in the lamina propria of the mucosa and on the serosa; there were also lesions of enteritis of various intensity. The lamina propria was infiltrated by numerous polymorphonuclear leukocytes, 80% of which were eosinophils. In the submucosa the leukocytes were less numerous, and again they were practically all eosinophils; they appeared to have no immediate topographic relationship to the cysts. Eosinophils could be seen in the sinuses and in a great number at the periphery of the lymph node in 2 patients. In one patient in whom eosinophils were abundantly present in the lymph node, some rhomboid, elongated, acidophilic crystals resembling Charcot-Leyden crystals were found within the reticulum. The authors attempted to elucidate the association between lymphopneumatosis cystoides and eosinophilia and came to the conclusion that the gases in the cysts are not able to produce eosinophilia. Lymphopneumatosis seems to result from the association of several factors, namely, gastrointestinal disturbances and acidification of the gastrointestinal content. However, the pathogenesis of the condition is still obscure.

Galactosemia: Genetic Considerations. R. Van Geffel, A. Devriendt, J.-P. Dustin and others. Arch. franç. pédiat. 16:158-184 (no. 2) 1959 (In French) [Paris].

Four infants afflicted with galactosemia were diagnosed by 2 criteria: (1) appearance of notable galactosuria after ingestion of milk and (2) abnormal increase in galactosemia after ingestion of 1.75 Gm. of galactose per kilogram of weight. These 4 infants were from 3 different families. In the first family the first 3 children died after serious symptoms; as a result, in the last 2 born in this family the diagnosis of galactosemia was suggested very early, based on the cited criteria. In the other 2 families, in spite of early diagnosis, many symptoms developed in a short time. In the 4 infants omission from the diet of foods with galactose was followed by a rapid remission of symptoms, and no sequel was observed. The parents of 3 of the infants had intolerance to galactose, which only an "oversupply" test could show. This indicates the role of heredity in this disease.

The aminoaciduria which accompanies galactosemia is frequently at a high level and may exist several days after the disappearance of galactosuria, when the patient is deprived of all galactose. The authors used methods of partition chromatography to estimate the amount of aminoacidemia and of aminoaciduria. These determinations showed the importance of "overflow" phenomena of the tubular resorption capacity, but some ascertainments permit the belief that there is some measure of intervention of purely renal factors.

A Functional Investigation of Liver Impairment Due to Poliomyelitis. G. Poli, G. Verdura and N. Svilokos. Minerva pediat. 11:215-226 (March 3) 1959 (In Italian) [Turin, Italy].

Laboratory tests were made on 49 poliomyelitic children to study the extent of liver impairment from a functional point of view. The tests indicated liver damage in 6 of 8 children on whom they were made during the acute stage of the disease. A marked drop in the level of gamma globulin was observed in the remaining 2 children; the alpha$_2$ globulin value was high, and the beta globulin not so high; marked hypoalbuminemia and hypoproteinemia were observed in one child. Some relationship between the extent of liver damage and the neurological involvement was found in some of the 8 children.

The tests in the other 41 children of the series were made 3 to 11 months after the acute episode of poliomyelitis. These children were divided into 3 groups according to the results of the tests. The first group, composed of 14 children, showed a normal protein picture, with the exception of a somewhat constant increase in alpha$_2$ globulin. In these children the serum lability tests gave negative results; bilirubinemia was normal or had increased only slightly; total cholesterinemia had reached maximal normal values in 3 children only, and it was slightly lower than normal in 1 child. The few changes present in these 14 children did not indicate a sclerotic effect of the hepatic lesion. The 6 children of the second group presented a normal total protein picture and an increase in globulin values which caused an inversion of the protein quotient. Electrophoresis revealed hypoalbuminemia and increased alpha$_2$, gamma, and, at times, alpha$_1$ globulin; colloidal lability tests were positive in all cases; van den Bergh's test gave results close to normal; bilirubinemia was close to normal; the values of cholesterol were normal in all children except one in whom they had increased. An accurate examination of the clinical history of each of these 6 children made possible the exclusion of poliomyelitis as the cause of these alterations. One child had suffered a lipid nephrosis, and the others had contracted Asian influenza a few days before the tests were made. The third group was composed of 21 children, all with a normal protein picture. Electrophoresis showed an increase in alpha$_2$ and, at times, in beta globulin; the gamma globulin level was low in all these patients. Other tests gave normal results. Gamma globulin values were low in 23 of the 49 children observed.

The authors believe that liver damage observed during an acute episode of poliomyelitis is benign even in extreme cases of hepatitis and that the pathological changes regress with no fear of liver cirrhosis even after a long period of time.

Acute Appendicitis in the Course of Measles: Description of 5 Cases. P. Nicola and L. Bertola. Minerva pediat. 11:237-242 (March 3) 1959 (In Italian) [Turin, Italy].

The authors report on 5 children operated on for acute appendicitis during the course of measles. The children, 5 to 8 years old, were observed at the University Hospital in Turin, Italy, during the period from April to July, 1957. All the children recovered and were discharged from the hospital 8 to 21 days after admission. Statistical data on the frequency with which acute appendicitis occurs during measles are not available, but the authors believe that it would be unwise to assume that such an occurrence is exceptional. The symptoms of appendicitis developed in the prodromal stage of the measles in one child, coincided with the cutaneous eruption in 3 other children, and developed when the exanthem had almost disappeared in the 5th child. The symptoms in 2 children were characterized by a gradual onset, with vague and diffused abdominal pain which later became localized and severe; in the other 3 children the symptoms were severe after their sudden onset. One child presented a hyperemic and edematous appendix free from adhesions, while 4 children presented an appendicular perforation, which was followed by circumscribed peritonitis in 3 cases and general peritonitis in the other. Two children suffered from intestinal occlusion as a late complication. A rapid and severe evolution of acute appendicitis constitutes the most characteristic symptom of the condition during the course of measles.

UROLOGY

Dissolution of Experimentally Induced Vesical Calculi in Rats by Sodium Phytate and Sodium Neutral Phosphate Treatment. D. F. McDonald and M. O. Orallo. J. Urol. 81:534-536 (April) 1959 [Baltimore].

The authors performed experiments on rats in which growth of vesical calculi was induced by implantation of magnesium nidi. The animals then were given high doses of sodium phytate and sodium neutral phosphate mixed in the ground laboratory chow. Both phytate and phosphate administrations were associated with complete dissolution of 50% of the experimentally induced calculi and reduction in size of those calculi not completely dissolved. These animal experiments confirm clinical reports and suggest that optimal dosage is of utmost importance in achieving dissolution of urinary calculi.

Partial Nephrectomy for Hypernephroma in a Solitary Kidney: A Case Report. W. K. Kerr, S. Anthone, R. Anthone and N. C. Carruthers. J. Urol. 81:509-511 (April) 1959 [Baltimore].

The authors report the case of a 46-year-old woman who was admitted to the Toronto General Hospital because of total painless hematuria for 5 days and suprapubic pain for 1 day. Cystoscopy revealed that bloody urine came from the right ureteral orifice and no left ureteral orifice was found. An intravenous pyelogram showed compression of the right upper major calyx with an irregular mass in the upper pole of the right kidney. A right thoracoabdominal incision was made through the 9th rib bed. The right renal mass was visible as a probable hypernephroma of the upper half of the kidney, and this was dissected free, exposing the renal pedicle. The renal artery was clamped and the kidney surrounded by Penrose drains filled with ice water to apply local hypothermia. After 11 minutes of cooling, the cor temperature had not fallen, but the surface temperature had fallen to 30.8 C (87.5 F). The tumor and a cuff of normal renal tissue were removed by sharp dissection. Microscopic examination of the operative specimen revealed a renal carcinoma, extensive areas of which had undergone hyalinization with scattered hemorrhage. Renal hypothermia was largely ineffective due to the large bulk of the tumor. This and the long occlusion time of the renal artery were probably the most important factors in producing acute renal failure postoperatively.

Dialysis was used because of the deteriorating clinical picture and the increasing acidosis. Its effects were dramatic and were followed by continued improvement in the clinical state of the patient. The serum electrolyte values gradually stabilized at normal levels, and the anemia corrected itself spontaneously. A satisfactory immediate result thus was obtained in the treatment of this patient, and continued improvement was observed 4 months after the operation. This is the third case of successful elective surgical treatment of a hypernephroma in a solitary kidney. It is believed to be the first case involving the postoperative use of dialysis.

Urogenital Tuberculosis in the Male: Investigations with Vesiculography and Urethrography: Preliminary Report. H. B. Mygind. Ugesk. laeger 121:448-454 (March 19) 1959 (In Danish) [Copenhagen].

Vesiculography in patients operated on for tuberculous epididymitis shows changes in the seminal vesicles and ductus deferens on the sick side in all cases and in unilateral epididymitis on the well side in about half the cases. On urethrography and rectal exploration changes in the prostate are found in almost all patients with tuberculous epididymitis. Since similar changes are equally often found in patients with renal tuberculosis but without epididymitis, it is seen that the prostate is always affected in urogenital tuberculosis. Renal tuberculosis was demonstrated in up to two-thirds of the patients with tuberculous epididymitis. Follow-up of patients operated on for tuberculous epididymitis will probably reveal active tuberculosis in many cases. Tuberculous infection of the urogenital system is, as a rule, extensive at the time when a tuberculous epididymitis is diagnosed. The course of tuberculosis in the pelvic organs is insidious, with few and vague symptoms. Tuberculous epididymitis is an important part symptom in tuberculous infection in the genital system.

Hemangioma of the Kidney. J. B. Wallach, A. P. Sutton and M. Claman. J. Urol. 81:515-518 (April) 1959 [Baltimore].

The authors report the occurrence of hemangioma of the left kidney in a 31-year-old woman who was admitted to the Bronx Municipal Hospital Center in New York with fever, chills, left flank pain, and hematuria. Intravenous and retrograde pyelograms revealed moderate hydronephrosis and a radiolucency in the left pelvis with the filling defect of the left upper calyx. Left renal exploration was accomplished, and a normal appearing kidney was observed. There were 3 prominent varicosities about the renal pelvis. The upper pole of the kidney was bivalved, revealing a pedunculated lesion on a narrow stalk. Nephrectomy was performed as the procedure of choice. The final pathological diagnosis was pedunculated capillary hemangioma of the kidney, arising from the renal papilla and protruding into the superior calyx. The postoperative course was uneventful.

Eighty-six cases of hemangioma of the kidney were collected from the literature. The lesion was almost always unilateral and was solitary in 77 of the 86 cases. Half of the patients were more than 40 years old, and age was not useful in differentiating hemangioma from carcinoma of the kidney. The diagnosis was rarely made clinically; a clue to the diagnosis may be the finding of hemangioma of the skin, but this is infrequent. Various methods of therapy are summarized, including nephrectomy. When the diagnosis of hemangioma can be established by gross and frozen-section examination of the locally excised lesion, the kidney should be closed, and irradiation therapy instituted. Irradiation therapy of hemangioma of the kidney, instead of nephrectomy, deserves adequate trial for the maximum conservation of renal parenchyma.

PATHOLOGY

Studies on Melanoma: II. Sex and Survival in Human Melanoma. L. P. White. New England J. Med. 260:789-797 (April 16) 1959 [Boston].

The author employs the term "melanoma" to denote a malignant tumor derived from the melanoblast (or melanogenoblast) which is capable of spread and metastasis; elsewhere it has been known as malignant melanoma, melanocarcinoma, or melanosarcoma. An investigation was started concerning possible differences in the growth of melanoma between men and women, when it was learned that melanomas, after transplantation into 2 strains of mice, grew 4 or 5 times as large in males as in females during the same period. Survival in human melanoma was studied in 439 determinate cases from a total number of 871 cases obtained from Stanford Hospital and from the tumor registry of the Department of Public Health of the State of California, which conducts follow-up studies for many of the hospitals in California. These cases were grouped according to the site of the melanoma (ocular or cutaneous) and the sex and age of the patient.

The literature was scanned with attention to reports detailing sex and age in patients with melanoma and reporting 5-year survivals. Some series showed a considerable difference in 5-year survival between men and women, and this difference invariably favored the survival of women. Most reports on melanoma, however, did not differentiate between men and women, so that no impression could be formed of the relative survival rates of the two sexes. All reports mentioning pregnancy indicated that pregnancy was a distinct threat to survival in women with melanoma, but none compared survival of pregnant women with that of nonpregnant women of the same age. Statements regarding the deleterious effect of pregnancy on the course of melanoma were based mostly on case reports and not on adequate statistical study.

Data obtained in the aforementioned 439 cases and from the literature suggested that the distribution of melanoma is roughly equal in the 2 sexes, but that survival is better in women than in men with melanoma, and that this difference in survival is statistically significant. Women with melanoma have a greater chance than men of living for 5 years, and the prognosis for survival beyond the 5-year period even more strikingly favors women. The prognosis for 5-year survival in both sexes decreases with advancing age. Although there is no direct evidence, the variation of behavior of melanoma at times of hormonal upheaval in human beings, together with better survival in women than in men, suggests the possibility that melanoma is under some sort of hormonal influence or control.

Experience with Smears of Aspirates from Bone Marrow in the Diagnosis of Neuroblastoma. P. C. Gaffney, C. F. Hansman and G. H. Fetterman. Am. J. Clin. Path. 31:213-221 (March) 1959 [Baltimore].

The recognition of neuroblastoma cells in bone marrow smears from patients with neuroblastoma and the diagnostic value of this finding have been established. The authors report observations on bone marrow smears from 31 of the 35 patients with neuroblastoma or ganglioneuroblastoma, who were observed at the Children's Hospital of Pittsburgh during the 4-year period from July 1, 1951, through June 30, 1955. The bone marrow aspirates were taken on one or more occasions from one or more sites. The sternum was usually the site when only one sample was taken. The tibia, spinous processes of vertebrae, and iliac crest were other sites of aspiration. In 13 of the 31 patients, only one sample was obtained. In each of the remaining 18 patients, from 2 to 6 specimens were taken, either as part of the original examination or at a subsequent examination. Smears were prepared from the aspirates, but no histological sections were made of the aspirated material, because, in the experience of the authors, the study of the sections adds nothing to the knowledge obtainable from smears. Sternal aspirations in infants and young children require great caution because of the danger of penetration of the needle beyond the sternum with damage to vital structures. In young infants tibial puncture may be a less dangerous procedure.

Characteristic tumor cells were found in 15 of the 31 patients. In 13 of the 15 positive cases, the smears of marrow contained tumor cells when the patients were first observed. In 11 patients, the examination of smears of marrow provided the first morphologic evidence of neuroblastoma. The recognition of neuroblastoma cells in smears of marrow suggests metastatic neuroblastoma. All 15 patients with marrow metastases, as revealed in smears, were dead within one year after diagnosis. The longest survival period was 11 months; the arithmetic average of survival time was 3.6 months. Of the 16 patients with proved neuroblastoma or ganglioneuroblastoma, in whom aspirates from bone marrow were negative, 7 are alive and well at the time of this report.

The presence of tumor cells in the bone marrow of patients with neuroblastoma is not dependent upon the existence of radiovisible bone lesions. The early bony metastases involve marrow spaces and hemopoietic tissue rather than osseous tissues proper. The involvement of marrow in neuroblastoma tends to be diffuse. In every instance in which smears of sternal marrow were positive and further search was made in other bones, one or more additional sites proved to be positive. This was true in 7 of the 15 positive cases. In the other 8 patients, no further search was made.

Investigators who have studied the morphologic characteristics of neuroblastoma cells in bone marrow smears have stressed the tendency of the cells to form ball-like clumps or mosaics. The term "pinwheel mosaic," as applied by some, is strikingly apt. The authors do not suggest that examination of smears of aspirates from marrow should replace other morphologic methods in the diagnosis of neuroblastoma, but in view of the nonspecificity of the presenting signs and symptoms in patients with neuroblastoma, the examination of smears of aspirates from marrow for tumor cells may often provide the solution for an otherwise baffling case.

RADIOLOGY

Roentgenokymographic Investigation in Patients with Patent Ductus Arteriosus Accompanied by, or Free from, Pulmonary Hypertension. C. Quaglia, R. Gentilli, and E. Ciambellotti. Minerva med. 50:233-249 (Jan. 31) 1959 (In Italian) [Turin, Italy].

Roentgenokymographic investigations were carried out on 21 patients with patent ductus arteriosus, who ranged in age from 6 to 35 years; 17 of them, having only slight or no pulmonary hypertension, underwent surgery, whereas the remainder were not operated on because of high pulmonary hypertension and the inversion of the shunt. The investigations began a few days before and were continued for 1 to 12 months after the operation. Postoperative roentgenokymograms recorded remission of the increased pressure of hilar arteries in those instances in which it was present before the operation. The width of the sphygmic wave of the pulmonary artery diminished in all the patients, and the pattern of the pulse curve tended to reflect low or normal blood flow. Decrease of the systolic wave was observed in 2 instances. The convexity of the diastolic part of the curve leveled off in 10 patients and attenuated in the remainder. The diastolic-systolic ratio diminished in all the patients. Roentgenokymograms of 4 patients, in whom patent ductus arteriosus was associated with considerable pulmonary hypertension, revealed the state of a perpetuating pulmonary high blood pressure and gradual diminution of the flow of pulmonary circulation. Short and distant roentgenokymographic inspections after the operation indicated that surgical therapy considerably corrected, although it did not completely remove, the anomaly underlying the pulmonary hypertension in these patients.

The Small Intestine in Whipple's Disease. W. Martel and F. J. Hodges. Am. J. Roentgenol. 81:623-636 (April) 1959 [Springfield, Ill.].

"Intestinal lipodystrophy" was the term suggested by Whipple, and he believed the disorder named after him to be due to abnormal fat metabolism. The disease has a progressive downhill course, with death within a few years. Polyarthritis which may be the initial symptom usually disappears after the onset of diarrhea. In about half of the cases diarrhea or abdominal pain is the presenting symptom. The diarrhea is intermittent; the abdominal pain may be crampy and may be associated with distention. Gross rectal bleeding and generalized purpura may be seen in the later stages of the disease. Emaciation and a peculiar gray-brown pigmentation of the skin are typical. Generalized, discrete, peripheral lymphadenopathy is frequently observed. Anemia is almost always hypochromic or normochromic microcytic. A flat oral glucose tolerance curve is characteristic, and there is usually an abnormal increase in fecal fat.

The authors describe their observations on 3 patients with Whipple's disease, giving particular attention to the roentgenologic changes in the small intestine. Two of the patients were men, aged 35 and 54 years, respectively. Both died, and autopsies were made. In one of these men cecal volvulus developed, which may have been coincidental. The third patient was a 43-year-old woman, in whom the diagnosis was verified by biopsy studies on a mesenteric lymph node, on the omentum, and on the duodenal mucosa. The roentgenologic findings in the 3 cases indicate that one can expect the appearance of the small intestine to be abnormal. Thickening of the mucosal folds was an outstanding feature in all 3 patients and was most marked in the duodenum and jejunum. Segmentation of the barium column into large, separated masses was consistently observed. The moulage sign, the apparent obliteration of the mucosal folds in the jejunum ("as if wax had been poured into it"), was not seen in the 3 patients presented here. It is emphasized that various conditions are capable of producing alterations in the roentgenologic appearance of the small intestine which are indistinguishable from Whipple's disease. It will usually be necessary to rely on the clinical and laboratory data in the differential diagnosis.

The wall and the mesentery of the small intestine are thickened in Whipple's disease. The mesenteric and retroperitoneal lymph nodes are enlarged, yellowish in color, and have a spongy appearance on sectioning. Microscopically, one notes a diffuse infiltration of the mucosa of the small intestine by large mononuclear macrophages which possess abundant granular cytoplasm imparting a foamy appearance to the cell. The cytoplasm stains faintly basophilic with hematoxylin and eosin and gives a positive reaction to periodic acid Schiff (P.A.S.) reagent. These cells are present in the mesenteric and retroperitoneal lymph nodes and have been demonstrated in peripercal lymph nodes as well. The lacteals in the small intestine are dilated and frequently contain these macrophages together with collections of neutral fat and fatty acids. The mucosal villi are swollen due to the cellular infiltration, and the submocosa may be edematous. Little attention was paid to the cytoplasm-rich macrophages until Black-Schaffer in 1949 showed that these cells reacted positively to the P.A.S. test. It is possible that the P.A.S. positive material is elaborated by the intestinal mucosa and phagocytosed by the mononuclear cells, or perhaps it originates within these cells. The abnormal protein-polysaccharide complex may be related to certain enzymes necessary for fat absorption and transport. A beneficial response of Whipple's disease to corticotropin, but not to cortisone, has been reported, and the possibility of a genetic factor in the etiology has also been suggested.

Acromegaly. H. L. Steinbach, R. Feldman and M. B. Goldberg. Radiology 72:535-549 (April) 1959 [Syracuse, N. Y.].

The authors report on 11 men, between the ages of 24 and 53 years, and on 16 women, between the ages of 30 and 73 years, with acromegaly from whom roentgenograms were obtained. Acromegaly, an insidious disease, is the result of increased secretion of growth hormone by a benign or, rarely, a malignant tumor of the anterior pituitary occurring during or after closure of the epiphysial cartilages. Symptoms and signs are due to the expansile growth of the neoplasm, the elaboration of excessive quantities of pituitary hormone, and the interference with other normal pituitary functions by pressure of the tumor on the uninvolved portion of the gland. All the tissues in the body are affected by the excessive quantity of growth hormone. In general, the response is one of hyperplasia and hypertrophy. The bones may increase in size, owing to accelerated endochondral ossification or oppositional bone growth. In some areas there is increased bone resorption. Some of the changes occurring in the bones are similar to those incident to the normal aging process, but are markedly accelerated and greater in degree. The usual sex differences in the appearance of the soft tissues and skeleton are exaggerated by the excessive quantity of growth hormone.

The diagnosis of acromegaly is primarily clinical. The roentgenologic diagnosis could be accurately established in an examination of the skull if the sella turcica were significantly enlarged and if this finding were accompanied by an elongated mandible with a wide angle and enlarged sinuses. The presence of a thick scalp and of hyperostosis of the inner table of the skull in women would further substantiate the diagnosis. However, this combination of morphologic changes was present in only a few of the patients, and in many of them a diagnosis of the disease by roentgenographic methods alone was not possible. Of particular significance in the patients was the presence of a marked thickening of the soft tissues of the fingers, toes, and scalp. This thickness diminished after successful treatment by irradiation or surgical removal of the pituitary gland, but the tissues did not revert to normal size. Another pertinent roentgenologic observation was the association of thickened articular cartilages (wide joint spaces) of the hands and wrists with hypertrophic changes of the adjacent periarticular surfaces. A peculiar constriction of shafts of the proximal phalanges and metatarsal bones of the foot was observed in most of the patients. The results of this study indicate that roentgenograms of the feet should be obtained, along with those of the skull and hands, in the routine evaluation of acromegaly. Concave posterior borders of the lumbar vertebrae were observed in 6 patients. This change could be due to increased molding resorption of the central posterior surfaces of the vertebral bodies as a direct result of the excessive quantity of growth hormone or, secondarily, of pressure by the enlarged soft tissues in the spinal canal.

Familial Pulmonary Alveolar Microlithiasis: Four Cases from Colombia, S. A.: Is Microlithiasis Also an Environmental Disease? G. Esguerra Gómez, E. Lichtemberger, A. Santamaría and others. Radiology 72:550-561 (April) 1959 [Syracuse, N. Y.].

The authors report the occurrence of familial pulmonary alveolar microlithiasis in 4 women, between the ages of 40 and 50 years, who were sisters and belonged to a family of 7 children (2 boys and 5 girls). This disease, which is characterized by the presence of innumerable minute concrements lying free within the alveoli, throughout the lungs, and unattached to the alveolar walls, is an extremely rare disease, and the 4 cases were the first to be discovered in Colombia. The results of roentgenologic and clinical studies, the course of the disease, and the anatomico-pathological findings on autopsy in the oldest of the 4 patients with the most advanced lesions were in accord with those reported by other workers in the 43 cases of familial pulmonary alveolar microlithiasis collected from the literature. In 3 of the 4 sisters, a pleural thickening over the minor interlobar fissure was a constant finding in the roentgenograms of the chest; none of these patients had cough. Cough is not considered a symptom of uncomplicated alveolar microlithiasis, and does not appear so long as cor pulmonale does not supervene. In the 4th patient who had the most advanced lesions and who died, there was, however, cough, either dry or with scanty sputum of the mucous type, and the roentgen-ray picture was that of cor pulmonale.

The electrocardiographic tracings of the 4 patients did not show definite myocardial damage in the ventricular complexes, except for a highly questionable blockage of the bundle of His. The earliest manifestations of the disease were dyspnea and cyanosis, which, however, were not proportionate to the severity of the lesions as revealed by the roentgenograms. In some patients these symptoms appear early, whereas in others they may be almost nonexistent even though the lesions are far advanced. The possibility that microlithiasis may not be exclusively familial but that environmental and dietetic factors may play a role in its onset in persons previously predisposed was suggested by the fact that the 4 patients lived all their lives in the same house and in the same locality, with the same environment and the same diet, while the other siblings who left home at an early age did not show any evidence of the disease. So characteristic is the roentgen-ray appearance that the roentgenologist who has once seen a chest roentgenogram of any of these patients, and who keeps in mind the paucity of symptoms, can make the diagnosis of microlithiasis with certainty, without waiting for histological confirmation.

Possibilities and Limitation of Roentgenographic Examination in Early Diagnosis of Bronchogenic Carcinoma. A. Giobbi, F. Calamari and E. Miradoli. Lotta contro tuberc. 28:1138-1144 (Nov.-Dec.) 1958 (In Italian) [Rome].

A mass roentgenographic examination conducted among 704,837 persons in Milan, Italy, revealed bronchogenic carcinoma in 1.98 persons per 100,000; the frequency among persons over 40 years of age (148,340) was 9.43 per 100,000. The carcinoma could still be treated by surgery in most of these patients. It appeared as an isolated mass in 16 patients and was accompanied by an atelectatic component in 2. The tumor, however, was no longer operable in 6 patients; in one it appeared isolated but with some metastases in the hilar-mediastinal lymph nodes, and in the other 5 it was accompanied by parenchymal atelectatic processes. As limitation of roentgenographic examination in early discovery of carcinoma, the authors list the following conditions: (1) failure of the examiner in recognizing early signs of bronchogenic carcinoma; (2) location of the tumor is such that radical operation is not allowed even in case of early diagnosis; and (3) histological characteristics of the tumor in cases of rapid local growth and rapid metastases. The authors believe that the optimal frequency of roentgenographic examination for constant control of bronchogenic carcinoma in a community is every year or two, but even this frequency may fail to reveal early enough the presence of tumor in some cases.

Myelography with Water-Soluble Contrast Substance: Analysis of 427 Myelograms. P. Kolstad and G. H. Solem. Nord. med. 61:306-309 (Feb. 19) 1959 (In Norwegian) [Stockholm].

Myelography with a water-soluble contrast medium (myelotrast, abrodil) is considered a reliable diagnostic examination for nucleus prolapse and a valuable supplement to clinical examination. An accuracy of 90 to 95% should be attainable. Completely lateral prolapse may escape myelographic demonstration, and other intraspinal conditions, such as arachnoiditis or vascular malformations, can myelographically resemble prolapse. From 1949 to 1957, a total of 427 myelograms were obtained for 393 patients, aged from 16 to 74 years. The diagnosis was incorrect in only 12 of the 173 patients on whom laminectomy was performed. Myelotrast undoubtedly exerts an irritating effect on medulla and nerve roots. A slight fall in blood pressure may be expected, and the injection should be done by an experienced person. The complications observed are not thought to justify departure from the method. The authors look forward to a less irritating, i. e., more isotonic, contrast medium.

Left Atrial Calcification. C. W. Vickers, O. W. Kincaid, F. H. Ellis and A. J. Bruwer. Radiology 72:569-575 (April) 1959 [Syracuse, N. Y.].

The authors report on 3 women, between the ages of 36 and 59 years, and 2 men, aged 44 and 57 years, respectively, in whom calcification in the wall of the left atrium was revealed by chest roentgenograms. All 5 patients had severe rheumatic heart disease with involvement of the mitral valve. Pure stenosis of the mitral valve was present in 4 patients who underwent mitral commissurotomy. The 5th patient had severe mitral insufficiency, and this patient was not operated on. Invariably the history of symptoms referable to rheumatic heart disease was of long standing, the range of its duration being from 7 to 51 years. The cardiac disability was severe in each patient. In addition to calcification in the wall of the left atrium, the roentgenologic findings in each patient indicated severe mitral heart disease with pulmonary venous hypertension. Calcification of the mitral valve of sufficient degree to be identified roentgenologically or surgically was noted in 3 of the 5 patients. The calcification of the left atrial wall was of such magnitude or in such a position in 3 of the 4 patients operated on that the surgeon was compelled to enter the left atrium by some approach other than the usual one through the auricular appendage. The patient, in whom the atrium was entered through the calcified posterolateral wall, died 24 hours postoperatively.

It is believed that entering the atrium through the calcified wall, through the normal atrial wall near the valve, or through a pulmonary vein—the 3 possibilities of approach to the mitral valve in case of calcification of large portions of the wall—may be associated with a greater than average risk. The total number of recorded cases in which the ante mortem diagnosis of calcification of the left atrial wall was established by roentgenologic methods is now 42. Because of the density of the heart shadow and the superimposed shadow of the thoracic spine, the calcification may not be observed in the conventional roentgenogram of the thorax. It may be best revealed by roentgenoscopy, by roentgenograms in the right anterior oblique and lateral projections, or by overpenetrated Bucky films made in the posteroanterior projection. It may be readily revealed by means of tomography.

Intramural Aortic Dissection as a Complication of Translumbar Aortography. E. F. Wolfman and D. E. Boblitt. A. M. A. Arch. Surg. 78:629-638 (April) 1959 [Chicago].

The authors report 4 men, between the ages of 37 and 62 years, with aortic and peripheral vascular disease, on whom translumbar aortography was performed. These patients died, 3 hours, 29 days, 4 days, and 12 days, respectively, after the aortography. Autopsy which was performed on 3 of the 4 patients revealed that 2 died as a direct result of a dissecting aneurysm of the abdominal aorta produced by the injected contrast medium. Although a dissecting aneurysm was proved at autopsy in the third patient, ventricular fibrillation and coronary insufficiency accounted for his death. In the case of the patient in whom permission was not granted for autopsy, it was conceivable that occlusion of the renal arteries occurred, but the presence or absence of dissection could not be substantiated. A more likely explanation for renal failure in this patient was the direct toxic effect of a large concentration of contrast medium acting on the renal parenchyma.

Intramural injection of contrast medium into the aortic wall is a common and potentially fatal complication of translumbar aortography. Of 302 translumbar aortograms obtained at the University Hospital and the Veterans Administration Hospital in Ann Arbor, Mich., between July, 1951, and June, 1958, there were 33 intramural injections, representing an incidence of 10.9%. They included the 4 reported by the authors. The following suggestions are offered for minimizing this complication. A short beveled needle should be employed in performing the aortic puncture. To minimize dissection of the frequently diseased medial layer by the needle tip, the aorta should be pierced as closely as possible to a 90-degree angle. Unless visualization of the upper abdominal aorta or kidneys is required, the needle should be inserted below the second lumbar vertebra. If a view of the upper aorta is necessary or lower aortic obstruction is suspected, the vessel should be pierced above the visceral branches, at the T-11 or T-12 level. No contrast medium should be injected unless a good pulsatile flow of arterial blood issues from the needle hub with each systolic thrust. A test picture should always be obtained after the injection of 5 cc. of contrast medium to detect aberrant locations of the needle tip. The aorta should be punctured only once, and the total amount of contrast medium injected should be limited to 25 cc.; frequently less will suffice. Rapid manual injection should be used, rather than high-pressure mechanical devices. A delayed abdominal roentgenogram should be obtained 20 minutes after the last injection of contrast material to detect abnormal retention of iodides by the kidneys and gastrointestinal tract.

BIOCHEMISTRY

Phospholipids of Human Red Blood Cells. G. B. Phillips and N. S. Roome. Proc. Soc. Exper. Biol. & Med. 100:489-492 (March) 1959 [Utica, N. Y.].

The authors feel that the wide disagreement in values reported for concentrations of individual phospholipids in human red blood cells indicates inadequacy of methods employed. Recently, it was shown that the main phospholipids in serum lipid extracts could be isolated and quantitated by chromatography on silicic acid. Concentrations of individual serum phospholipids in these studies were at variance with many previously reported values. In the present study, the same chromatographic method was used to isolate and quantitate the main phospholipids of red blood cells of 3 male and 3 female apparently healthy young adults in the fasting state. Three extractions of hemolyzed red blood cells were routinely performed, after it was found that the first 3 extractions removed probably more than 95% of the total extractable phospholipid. Chromatography of red blood cell lipid extract on silicic acid revealed the following main components: (1) ethanolamine-containing and serine-containing phospholipid, (2) lecithin, (3) sphingomyelin, and (4) lysolecithin. No previous investigators reported the presence of lysolecithin, which comprised about 2% of total red blood cell phospholipids. It is unlikely that this represented adsorbed serum lysolecithin, as the red blood cells were washed 3 times, or that it was produced as an artifact during the extraction or isolation procedure. It is of interest to note the striking contrast in the relative proportions of individual phospholipids in red blood cells as compared with serum, especially since there is evidence for exchange of phospholipids between these 2 compartments.

The values found for relative concentrations of individual serum phospholipids with the method described here were at variance with results obtained by others. Previous reports revealed considerable variation between normal subjects in the same series, as well as between series of different investigators, suggesting inadequacies in methods employed. The method described in this report resulted in relatively good agreement between duplicate samples and rather slight variation between subjects. Moreover, the present method seemed relatively simpler than previous methods and was carried out on only 2-ml. aliquots of packed red blood cells, although a considerably smaller quantity could have been used. At least as much lipid phosphorus appeared to be extracted as with previous methods.

Comparative Study of the Effect of Corn Germ Oil and Butter in Experimental Dyslipidosis in the Rat. C. Briot, J. Carlotti, P. Laudat and others. Presse méd. 67:543-545 (March 21) 1959 (In French) [Paris].

Experimental dyslipidosis was produced in 140 male Wistar rats by the administration of 14 diets differing chiefly in the character of their lipid overloading with either butter or corn germ oil. Each diet was given to a group of 10 rats for from 21 to 30 days, after which the animals were killed and their lipid status determined. Comparison of the findings in the groups that received 2 diets identical in general composition but differing in the type of lipid calories supplied, i. e., butter in one diet and corn germ oil in the other, revealed an absolute parallelism in the lipid formulas and a close parallelism in the lipoprotein reactions. Some doubt, therefore, in regard to the possible effect of unsaturated fatty acids on the lipid-protein balance seems to be warranted. It may be, as some works tend to show, that the provision of large quantities of unsaturated fatty acids, while permitting the persistence of lipid-protein imbalance, especially hypercholesterolemia, is nevertheless unfavorable to the deposition of lipids in the walls of the arteries. This point of view, however, is entirely foreign to that expressed by the American authors of the original work on this problem.

The literature reflects the differences of opinion between authors who have studied the action of unsaturated fatty acids in man and those whose studies, constantly less favorable, have been carried out in the rat. One reason for these differences may perhaps be found in the small number of patients who have actually been studied well, so that the favorable results might be attributable to a fortunate chance. The chief criticism that can be addressed to human experiments, however, is a lack of distrust in regard to possible psychological factors: thus, the use of a placebo seems to diminish considerably the part supposedly played by the introduction of unsaturated fatty acids into the diet.

The results of the present animal experiments, on the other hand, do not necessarily or even probably hold good for man. The causes of the dyslipidosis sometimes found in patients with atherosclerosis are, in fact, not known, and certainly it is never associated with alimentary errors as gross as those imposed in this study. The signs of atherosclerosis in a given patient may be the anatomic sequelae of an earlier humoral disease of which it is useless to try to find any biochemical traces. Nevertheless, humoral changes must necessarily be relied on, at least in human experiments on atherosclerosis, but in studying them care should be taken to use a large enough series and to counteract psychological influences by the rational administration of placebos.

Effects of Dietary Fat Upon Polyunsaturated Fatty Acids of Blood in Patients with Multiple Sclerosis. B. Gerstl, W. E. Davis Jr., J. K. Smith and others. Proc. Soc. Exper. Biol. & Med. 100:534-538 (March) 1959 [Utica, N. Y.].

Two schools of thought on the etiology of multiple sclerosis have recently gained prominence; one suggests that an allergic reaction is involved, the other that an enzymatic or metabolic defect underlies recurrent attacks of demyelination. The authors feel that their own observation that some patients with multiple sclerosis revealed higher plasma levels of dienoic acid than did controls, together with the dietary studies of Swank and the increased chylomicron index noted by Skillen and others, warrants further investigation of the lipid metabolism in this disease. A baseline blood sample was obtained after a patient with multiple sclerosis had been on average hospital diet, including approximately 20% protein, 28% fat, and 52% carbohydrate. Then, the test patients and contratest patients all received a nearly eucaloric diet with soybean oil as main source of polyunsaturated fatty acids (PUFA). Blood was obtained after overnight fasting. Clotting of blood was prevented by addition of dry potassium oxalate. The cells were separated by centrifuging at 3,000 rpm. Plasma was extracted and total lipids and cholesterol determined as in previous investigations. The PUFA's were measured by the method of Herb and Riemenschneider. Measurement at 374 mμ was included, and the PUFA's were calculated according to Hammond and Lundberg. Separation and estimation of PUFA's in red blood cells were carried out as described elsewhere.

Since ratios of individual lipids to total lipids and those between the 2 groups of structurally related PUFA's are more revealing than data on individual lipids, the authors also report their results as ratios. The different ratios obtained are listed, and some of the data obtained are compared with those of other investigators. The concluding summary emphasizes that a decline of cholesterol/lipid and of tetraene/PUFA and an increase of PUFA/lipid as well as diene/PUFA ratios were observed in both groups of patients. Differences between the 2 groups are represented by significant decline of triene/PUFA ratio in the contratest group and, conversely, by a rise of triene/tetraene ratio in the patients with multiple sclerosis. Studies on the red blood cell lipids did not reveal any significant changes in the ratios, though they reflected to a slight degree the changes in plasma lipids.

MSH-like Substance from Human Placenta. H. H. Varon. Proc. Soc. Exper. Biol. & Med. 100:609-610 (March) 1959 [Utica, N. Y.].

A melanocyte-stimulating hormone (MSH) from the pituitary, which is of functional importance in lower animals, has been known for several years. Interest in this hormone was renewed in 1954 after Lerner and co-workers showed that MSH had a role in human physiology. These investigators also reported that blood and urine levels of this hormone were elevated during pregnancy. The author of this paper describes studies that aimed at isolating MSH from human placenta. The isolation procedure employed is a modification of that employed by Lerner and others for preparation of pituitary MSH. Full-term placentas, of an average weight of 550 Gm., were collected from Chicago Lying-in Hospital soon after delivery, and then extracted individually.

The final product of extraction averaged 120 mg. per placenta. The assay employed was similar to the in vitro frog skin method. However, the skin of Anolis carolinensis (chameleon) was substituted because of certain advantages. Selected lots of hog pituitary MSH were used as standards. The material extracted was a tan powder readily soluble in water. The activity decreased greatly within a matter of weeks during storage at room temperature. Loss of activity was slowed down by refrigeration. The substance caused darkening of Anolis carolinensis skin similar to that caused by hog pituitary MSH. A table lists results of assays of MSH preparations from 10 placentas. The average concentration was about 3.05×10^2 units per milligram. This activity is much less than the reported value for pure MSH from hog pituitary of 5×10^7 units per milligram. The material had a potency 1/200 to 1/300 of that found in MSH preparations from hog pituitary.

The material seems to be present in concentrations greater than can be accounted for by its being derived from placental blood. Conjecture regarding the biological significance of placental MSH is summarized as follows: The rapid decline of MSH values in blood and in urine soon after delivery might be due to loss of the placenta containing large quantities of this substance. Whether the formation and rapid postpartum loss of much of the increased dermal and mucosal pigmentation commonly noted during pregnancy (chloasma) is also related to placental MSH requires further study.

Effect of Spirolactone SC 8109 on Renal Function in Normal Human Subjects. R. A. Wiggins, M. E. Hutchin, J. V. Carbone and P. D. Doolan. Proc. Soc. Exper. Biol. & Med. 100:625-627 (March) 1959 [Utica, N. Y.].

A natruretic effect of synthetic steroids (spirolactones) has been demonstrated in rats, dogs, and human subjects, but it has also been shown that these spirolactones are virtually ineffective in the absence of mineralocorticoid and that effects upon urinary electrolyte excretion are constant so long as a constant ratio of spirolactone/mineralocorticoid is maintained. It was the purpose of this study to examine more carefully renal function in the normal human subject under the influence of endogenous aldosterone with and without administration of a spirolactone. The substance used was 3-(3-oxo-17beta-hydroxy-19-nor-4-androsten-17alpha-yl)propionic acid gammalactone known by the code name, SC 8109. Five normal, male, human subjects were studied by the classic clearance techniques during salt deprivation before and after therapy with the steroid-17-spirolactone, SC 8109. No change in the glomerular filtration rate or effective renal plasma flow could be demonstrated, but a definite sodium diuresis and potassium retention occurred in response to the spirolactone. A small increase in free water clearance was seen in 4 of 5 subjects studied. These observations localize the effect of spirolactone to the renal tubule.

PUBLIC HEALTH

Lung Cancer and Cigarette Smoking. R. Doll. Acta Unio internat. contra cancrum 15:417-423 (no. 2) 1959 (In English) [Louvain, Belgium].

The author reports the results of 2 studies on lung cancer and cigarette smoking and reviews the various hypotheses which have been suggested to account for the results. Data on 187,783 men, between 50 and 69 years of age, who died of lung cancer in the United States have been compared with data on 24,354 men, aged 35 years or over, who died of the same disease in Great Britain. The first group was followed up for nearly 4 years, and the second for more than 6 years. The mortality rates among all the men, including nonsmokers and smokers, were about 10 times greater than the rates among nonsmokers, and the mortality rates among heavy cigarette smokers were about 20 to 30 times greater than those among nonsmokers. The mortality rates among cigarette smokers were substantially greater than the rates among other types of smokers, and the mortality rates among mixed smokers of cigarettes and other types of tobacco were intermediate. The mortality rate was lower when smoking had been stopped for 1 to 10 years, and was substantially lower when smoking had been stopped for 10 years or more.

The author concludes that the association of lung cancer and cigarette smoking is not an artifact resulting from the method of study. It does not necessarily follow that smoking causes the disease. It is suggested (1) that smoking determines the site of cancer appearance, (2) that the precancerous condition induces smoking, and (3) that smoking and cancer result from a common factor (heredity, alcohol). The principal observations which have been cited as incompatible with the theory that cigarette smoking is a causal factor in the production of the disease are (1) the increasing disparity in smoking habits, (2) the disproportion between the mortality from lung cancer and the cigarette consumption in different countries, and (3) the conflict of evidence with regard to the apparent effect of inhaling. These 3 objections raise questions of considerable theoretical interest. Many more data are required before they can be answered completely. It seems reasonable to conclude that none of the data provide a compelling reason for abandoning the hypothesis of causality.

Epidemiologic, Experimental and Histological Studies on Metal Cancers of the Lung. W. C. Hueper. Acta Unio internat. contra cancrum 15:424-436 (no. 2) 1959 (In English) [Louvain, Belgium].

The author presents data from the literature concerning environmental and occupational exposure to carcinogenic metals, their carcinogenic potency, and their relation to the causation of cancer of the lung. These data indicate that respiratory contact with these metals plays probably a more important role in the determination of general and occupational incidence rates of lung cancers than has been assumed in the past by many investigators. Recent studies on the distribution of certain metals in the atmosphere of some American cities suggest that lung cancer hazards for residents of industrialized urban areas not only may be due to organic chemicals but may, perhaps in part, be related to the presence of carcinogenic metallic dusts. The marked differences in the concentrations of various metals in the atmosphere of the numerous cities analyzed, moreover, suggest that these differences may have contributed to the striking variations in lung cancer death rates noted recently in a survey of 163 American metropolitan areas. This observation does not support the allegation that local differences in smoking habits mostly account for the differences in lung cancer death rates.

The author reports on his own experimental investigations with radioactive metals, chromium, and nickel, which have succeeded in the production of cancers of the lung and of other tissues in animals exposed to certain inorganic chemicals (radioactive metals, nickel, chromium, arsenic, asbestos, and, possibly, iron oxide and beryllium); these are known to be or are suspected of being responsible for an excessive occurrence of cancers of the lung, larynx, nasal cavity, and nasal sinuses in members of special worker groups. The histological, hyperplastic, and neoplastic lesions elicited in the lungs of experimental animals by nickel-containing and chromium-containing compounds were similar or identical with those seen in men exposed to the same and similar inorganic carcinogenic dusts, fumes, and vapors. The cancerous reactions observed in animals and man include carcinomas of the squamous-cell, round-cell, and adenocarcinomatous types. Animals exposed to nickel and chromium exhibit, moreover, sarcomatous reactions. Since there is abundant human and experimental evidence indicating that the same exogenous carcinogen is capable of producing cancers of different histological types, the recently advanced claim that squamous-cell and round-cell carcinomas of the human lung are predominantly, or almost exclusively, caused by cigarette smoking has no sound scientific or factual basis.

Salmonellosis Traced to Sea Gulls in Ketchikan Area. A. N. Wilson and Mrs. R. Baade. Alaska Med. 1:18-19 (March) 1959 [Anchorage].

It has been observed that, with the onset of the storms of early winter, the sea gulls leave the water front of Ketchikan and fly inland to Ketchikan Lake for shelter. Epidemics of gastrointestinal disease, generally referred to as "stomach flu," are often observed at this time of the year. In November and December, 1953, such an outbreak was traced to sea gulls at Ketchikan Lake, which is the main source of the water supply of the town. Thousands of gulls were at the lake at that time, and the water showed gross contamination. Birds are known to be carriers of Salmonella organisms. Of 14 sea gulls collected for study, one was found to harbor Salmonella (paratyphoid) organisms. Stool specimens obtained from hospitalized patients during the epidemic were also found to contain these bacteria. Typing of the organisms isolated from the gull and from the patients proved that all were of the type Salmonella manhattan, an organism of the paratyphoid C group. The authors cite additional reports on the pollution of water supplies by sea gulls, including instances in Massachussetts and at various points along the Pacific coast in Canada and the United States.

BOOK REVIEWS

The Practical Evaluation of Surgical Heart Disease: The Grover Clinic. Written and compiled by Robert G. Trout, M.D. Edited by Robert P. Glover, M.D. Medical illustrator: Joseph Sunner. Heart sounds recorded by J. Scott Butterworth, M.D. [Adapted from American Medical Association convention exhibit (June, 1957) which was awarded Billings Gold Medal.] Cloth. $10. Pp. 132, with illustrations and one 45 r. p. m. recording. Blakiston Division, McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E. C. 4, England; 253 Spadina Rd., Toronto 4, Canada, 1959.

This manual was prepared primarily as an uncomplicated and ready reference work to help the busy physician in his everyday professional tasks. The following subjects are presented: simplified physiology, radiographic interpretation, electrocardiographic interpretation, patent ductus arteriosus, coarctation of the aorta, vascular rings, pulmonary stenosis, interatrial septal defects, interventricular septal defects, tetralogy of Fallot, transposition of the great vessels, mitral stenosis, mitral insufficiency, aortic stenosis, aortic insufficiency, coronary insufficiency, cardiac catheterization, angiocardiography, and a bibliography. Each subject receives about five pages in the book and contains a drawing of the lesion, a discussion in outline form, roentgenograms, electrocardiograms, and a comment on the history, examination, and treatment of one or more illustrative cases. The presentation of each subject is brief and easily understood. This manual contains a wealth of information based on the extensive experience of the authors. If a practitioner were desirous of having a surgeon discuss one of these subjects, this is about what the latter would say in a brief discussion, accompanied by illustrations. This book is a primer on these subjects, and as such it is valuable.

No reference is made to such other cardiac conditions that concern the surgeon as acute and chronic compression of the heart, penetrating and nonpenetrating wounds of the heart, tumors of the heart, foreign bodies in the heart, the physiology of localized versus generalized anoxia in the heart, self-electrocution of the heart, and reversal of the death factor after it appears. These subjects also concern the practitioner but they are not common, except electrocution in hearts that are structurally too good to die. Prevention of electrical death and reversal after it occurs should be included in a modern treatise on cardiac surgery. This manual, however, covers a lot of ground in a concise and understandable way, and it is highly recommended.

Enzymopathologie: Enzyme in Klinik und Forschung. Von Dr. med. Roland Richterich. Cloth. 128 marks. Pp. 703, with 132 illustrations. Springer-Verlag, Heidelberger Platz 3, (1) Berlin-Wilmersdorf (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, Germany, 1958.

The author has been a student of enzymology, first in the departments of anatomy and of internal medicine at the University of Basel and, more recently, in the United States in the departments of cancer research, internal medicine, and pharmacology of the Boston University School of Medicine. He is co-author of publications dealing with hyaluronidase, urease, the effect of benzidine on liver, phosphatase, hydrogenase, and others. Thus he is well qualified to discuss authoritatively a subject which has become increasingly important for the understanding of human physiology and pathology. In the course of the extremely rapid growth of the knowledge in this area, it has become difficult to keep up with the literature even of one's own country, to say nothing of publications in other countries. The purpose of this book is to supply a critical digest of what is known of the role of enzymes in pathogenesis of disease, at least, as of the date of writing.

The subject is treated in three parts. Part 1 deals with the biology and physiology of enzymes. In part 2, general aspects of enzymopathology are presented. Inheritance of enzyme systems, the role of enzymes in the metabolism of proteins, carbohydrates, lipids, porphyrin, hemoglobin, and nucleic acid, in nutritional disturbances, and in hormone metabolism are among subjects discussed in detail. The role of enzymes in cancer, in the various aspects of proteolysis, and in the reactions of the body against external damaging agents are some of the other topics. Special enzymatic pathology is treated in over 300 pages of part 3. The role of enzymes in the lesions of connective tissue, of the osseous system, muscles, cardiovascular system, stomach, pancreas, liver, kidneys, and male sex organs are covered in great detail. The name and subject indexes are well organized.

The author has done a good job of assembling much of the material in the bibliography and presenting it in the form of a coherent text. In the field of causative relation between enzymes and human pathology there are not many textbooks of this type, and contributions of this sort are bound to be useful. However, this book, like others of the same kind, suffers from an inevitable weakness that cannot be avoided in ambitious projects undertaken by a single author. Some parts are more extensively treated than others. An example of a field that

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

could be improved by bringing the background knowledge up to date is the discussion on anaphylaxis and proteolysis in the sixth chapter of the second part of the book (page 248). The observations made in the last 10 years by H. Tabor, R. W. Shayer, S. A. Karjala, and others with respect to the metabolism of histamine have not been included. The most "recent" references on the subject of histamine date back to 1951.

Despite this and other similar shortcomings, ideas are clearly presented throughout the text, and this makes the book highly commendable not only for the specialist, and the professional investigator, but even more so for the interested physician who tries to acquire a better understanding of the biochemistry of human disease.

Leprosy in Theory and Practice. Edited by R. G. Cochrane, M.D., Ch.B., F.R.C.P. With foreword by Sir George McRobert, C.I.E., M.D., F.R.C.P. Cloth. $15. Pp. 407, with 190 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; John Wright & Sons, Ltd., 42-44 Triangle West, Bristol 8, England, 1959.

This new, comprehensive textbook on leprosy and its management was compiled from the contribution of 24 students and practitioners in the field. The editor and major contributor is a dedicated and hard-working scholar whose travels have kept him in close touch with colleagues in those areas of the world where leprosy is endemic. He writes easily with authority and from long familiarity with his subject.

The chapters are in the familiar sequence of a text that deals with a communicable disease, exploring in order the history, bacteriology, epidemiology, pathology, immunology, clinical course, complications, treatment, prognosis, and prevention of the disease. The pace of the text changes as chapters by the contributing authors introduce detailed accounts of special problems and their management. The chapters on the acid-fast bacteria and on other mycobacterial diseases provide studies of the footings upon which further knowledge of the causative organism of leprosy will undoubtedly be built. The work on epidemiology shows the puzzles and contradictions that experience with leprosy provides to the field worker. It is difficult to derive sets of principles from observations gathered, and the sound conclusion is that "statements which apply in one area may not apply in another area."

An interesting chapter on sensory and neurohistological changes in leprosy follows the chapter on the pathology of the disease. There are very thorough presentations on involvement of the eyes, the care of the feet, and physical therapy methods for the relief of deformity. The excellent chapter on the surgical management of deformity, particularly of the hand, is well illustrated and should be useful to orthopedic surgeons concerned with restoring the function of hands crippled by other diseases of the peripheral nerves. There are 10 appendixes on topics that present problems to clinicians, surgeons, laboratory workers, and public health administrators. There is a surprisingly small number of repetitions or of contradictions in a book composed of chapters by authors whose laboratories and clinics are physically separated from each other by oceans.

There is a theme in the foreword, the chapters, and appendixes that reiterates many times the need for an objective examination and an understanding of this enigmatic disease, without emotional bias. It is expressed in many ways with sympathy for the plight of the patient. For example, the chapter on deformity begins by recognizing that visible mutilation frequently associated with the disease has maintained an unreasonable public rejection of these patients. Another chapter shows sensitivity to the hope that can now be encouraged in patients with leprosy and the misery and fear that still haunt them.

The editor and the contributors are all practical men faced with the need to combat a great clinical and public health problem. The only criticism that one can make of this useful book is that it devotes too little space to speculation and to theory. Each contributor adapts theory to his needs so that it becomes "practice." One gets the sense from this book that leprosy as a topic of study can serve as a springboard into the study of medicine and that the many unsolved problems in this disease will eventually be mastered by a multidisciplinary approach.

Instrumentation in Anesthesiology. By William H. L. Dornette, M.D., Professor of Anesthesiology and Head of Department, University of Tennessee College of Medicine, Memphis, and Verne L. Brechner, M.D., Assistant Professor of Anesthesiology, University of California School of Medicine, Los Angeles. Cloth. $8. Pp. 242, with 130 illustrations. Lea & Febiger, Washington Sq., Philadelphia 6, 1959.

Medical instrumentation is a field of constantly increasing ingenuity, particularly since World War II. At least one American graduate school now offers opportunities for advanced studies in this imaginative and eminently useful branch of invention. A volume that includes descriptions of all the devices and instruments currently applicable to anesthesiology has long been needed. This book satisfies that need. The authors proceed from such fundamental but salient considerations as safety precautions, basic physics, and electrical interference to the highest developments which instrumentation has thus far reached, meaning servomechanisms and central monitoring systems.

This presentation of a diverse and complex subject is unusually well done. The illustrations in many cases help to reduce what otherwise would have been a lengthy description. The reader who wishes additional information, particularly from authorities in the field who did pioneer work in the development of a given instrument or procedure, is provided with references to such studies. The authors lay down six fundamental requisites which, they believe, must be satisfied if a monitoring device or, indeed, any instrument applicable to anesthesiology, is to be acceptable. These are efficient performance, practical size, simplicity of operation, equitable cost, minimal nuisance to patients and others, and maximal safety. The book has great potential usefulness, since every technique and procedure it describes should contribute in some measure to improvement in the care of the surgical patient.

Asexualization: A Follow-up Study of 244 Cases. By Johan Bremer, Medical Director, Gaustad Mental Hospital, Oslo, Norway. Cloth. $5.50. Pp. 366. The Macmillan Company, 60 Fifth Ave., New York 11; *Oslo University Press*, Oslo, Norway, 1959.

From time to time through the years someone comes up with the suggestion that sexual criminals, or persons who might become such because of uncontrollable sexual urges, ought to be castrated. It is not always clear whether the suggestion has in mind the protection of the public or the penalizing of the individual, but the suggestion is made nevertheless. The practice of castrating criminals has never become popular in the United States and, in fact, in no state is it a legal procedure. It is legal in a number of European countries, however, and this book reports on a series of 244 sex offenders who were castrated under the Norwegian law between 1935 and 1949. The study analyzes in detail the changes in physical and psychic states, emotional reactions, and sexual life brought about in the 216 men and 28 women who were castrated under this law. Psychiatrists especially will be interested in the individual case histories.

So far as castration may be the answer to the problem of the sexual criminal, the conclusions of the report are quite definite. The study of the male castrates concludes: "In general, castration is only of therapeutic significance in behavioral disturbances involving an urge for sexual relief. No general effect of pacification has been encountered at all, no sedative influence on exaggerated affections, no harmonization of emotional life, no 'resocializing' influence on asocial or antisocial behaviour beyond the sexual sphere." About women castrates the report concludes: "Nobody castrated in the hope of pacifying has become easier to handle, and clinging and petting oligophrenics continue to do so. . . . As far as it is possible to judge from such unreliable, psychopathological material, sexual reactivity and activity are not essentially changed . . . . The results of the legal castration of women seem so uncertain and poor that there is definitely doubt as to its justification."

This book should be of great value and interest to lawyers, penologists, and psychiatrists.

The School Health Program: A Textbook for Teachers and for Other Professional Personnel in School Health. By Alma Nemir, M.D., Professor and Director, Division of Health Education, Department of Health, Physical Education, and Recreation, College of Medicine, University of Utah, Salt Lake City. Cloth. $6. Pp. 428, with 70 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

Written by a physician, with assistance from numerous educators, dentists, and public health personnel, this volume gives a good over-all view of a typical school health program.

The amount of attention given to the details of the health service program is greater than is customary in books describing the general school health program. Part 1, "The School Child: His Normal Health Status and Common Health Problems," discusses 16 areas of health interest from the point of view of both health service and health education, with emphasis on the role of the teacher, administrator, nurse, doctor, and others on the school health team. Part 2, "The School Health Program," covers the administrative organization of the school health program, including environment, services, education, and evaluation.

Each chapter is followed by a bibliography of additional sources of information and a list of materials for teachers to use in schools. The appendixes include a list of resource agencies, examples of school health record forms, and methods of program evaluation. Repeated reference is made to publications of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, as well as to other committees and commissions of these and other recognized authorities. The book's universal application is limited, however, by being strictly concerned with the specific school health situation created by the statutes and traditional practice in Utah. Nevertheless, school health personnel who follow this book should be able to develop a reasonably good program.

Physiology of Muscular Activity. By Peter V. Karpovich, M.D., M.P.E., Research Professor of Physiology, Springfield College, Springfield, Mass. Originally by Edward C. Schneider, M.P.E., Ph.D., D.Sc. Fifth edition. Cloth. $5.50. Pp. 368, with 83 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

The present edition is a revised and expanded version of a book recognized for a quarter of a century as an authoritative compilation of useful research in the physiology of exercise. A new chapter on muscle training has been created by dividing a former chapter. New material has been added on the effect of warming up on athletic performance, the heart and training, the relation between physical fitness and intelligence, a comparison of isotonic and isometric methods of muscle training, and other related factors. To serve as a guide to those using this book for study, each chapter is followed by a list of questions suitable for classroom discussion or self-evaluation.

A bibliography of 524 references, each keyed by number to the place of its discussion in the text, makes this a source book for physicians and physiologists concerned with sports medicine, physical educators and coaches responsible for the training of persons engaging in physical activity and athletic programs, and for those involved in research in physical activity.

Dangerous Marine Animals. By Bruce W. Halstead, M.D., Director, World Life Research Institute. Cloth. $4. Pp. 146, with 87 illustrations. Cornell Maritime Press. Cambridge, Md., 1959.

This book was written after 14 years of medical research on marine organisms. Dangerous animals are those that bite or are poisonous to man. This is a practical and instructive guide to their identification, world-wide geographical distribution, habits, noxious effects, and the treatment and prevention thereof. The opening chapter is a brief résumé of the manner in which knowledge of dangerous marine organisms has evolved. Following chapters deal with marine animals that bite (sharks, moray eels, and giant clams); those that sting (jellyfish, cone shells, and stingrays); and those that are poisonous to eat. This last chapter is not concerned with illness due to bacterial food poisoning, but rather with marine animals whose flesh may contain toxic substances under certain conditions. Physicians should be particularly interested in the sections on medical aspects which describe types of wounds, symptoms of poisoning, and recommended treatment. The practical value of this book is increased by numerous photographs and detailed drawings that show the specimen in its natural habitat and illustrate various features of anatomic significance. It is unusual to find authoritative and comprehensive data of this type presented in a popular style. Physicians, first-aid workers, biologists, and skin divers alike should find this a useful and valuable handbook.

The Plasma Proteins: Clinical Significance. By Paul G. Weil, B.A., M.D.C.M., M.Sc., Director, Transfusion Service and Assistant Physician, Royal Victoria Hospital, Montreal. Material published in American Practitioner & Digest of Treatment, September, 1958. Cloth. $3.50. Pp. 133, with 2 illustrations. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada, 1959.

Plasma proteins play a dominant role in the pathogenesis of a variety of diseases and clinical syndromes. The names of some proteins have become the names of diseases, e. g., agammaglobulinemia, cryoglobulinemia, and macromolecular syndrome. Consequently, at least slight familiarity with plasma proteins is essential nowadays for the understanding of many diseases and for the diagnosis and intelligent therapy of some. The busy physician, be he generalist or specialist, can rarely afford the time to look for information regarding biochemistry in the many textbooks on the subject. This pocket-sized book attempts to bridge the gap between what the practitioner needs and the sources of the required information in books and special journals. The specific items discussed in this book include albumin, fibrinogen, globulins, liver disease, pregnancy, infancy and old age, hemorrhagic disorders, amyloidosis, and other topics. The treatment of these complex subjects is aimed at the person without specialized education in chemistry. The author has achieved what he set out to do. The book is excellent for a quick review of an important subject and for occasional consultation, which will be facilitated by the well-organized subject index.

Tuberculosis Medical Research: National Tuberculosis Association 1904-1955. By VargVinia Cameron and Esmond R. Long, M.D. Historical series no. 9. Cloth. $5. Pp. 325. National Tuberculosis Association, 1790 Broadway, New York 19, 1959.

This is a historical résumé of the research in tuberculosis first recorded by leading proponents from their own laboratories and reported largely at the annual meetings of the National Tuberculosis Association commencing in 1904. The realization of the importance of such research in the solution of the problem of controlling tuberculosis, and that the necessary funds came primarily from the sale of Christmas seals, stimulated the leaders of the abovementioned organization in 1921 to create a definite program of grants-in-aid. Later this program was extended to the medical division, the American Trudeau Society. Thus there came into being one of the first research programs on a national scale supported by public contribution, the forerunner to the many national research programs now operating. This treatise contains a section on the financial aspects of grants-in-aid. Those interested in chest diseases, particularly tuberculosis, will wish to study this important phase of the work of the National Tuberculosis Association.

Principles of Peripheral Vascular Surgery. By S. Thomas Glasser, M.D., C.M., F.A.C.S., Associate Clinical Professor of Surgery, New York Medical College, New York. Cloth. $12.50. Pp. 410, with 32 illustrations. F. A. Davis Company, 1914-16 Cherry St., Philadelphia 3, 1959.

The unprecedented development of vascular surgery has brought forth a number of new monographs on this subject. Among these, Glasser's new contribution is characterized by its clarity of style and by its comprehensive bibliography. There are few illustrations, hardly any of them original. The extensive material lacks organization and some subjects are given undue emphasis. The total impression is that of a broad literary survey, uncritically presented. The general practitioner or the general surgeon performing some vascular operations will not get a balanced picture of the field from this book. For those actively engaged in this specialty, it is a useful source of reference.

QUESTIONS AND ANSWERS

TYPHOID CARRIERS

To the Editor:—*It is generally accepted that typhoid immunizations reduce the incidence and severity of clinical typhoid by producing a significant level of antibody. Clinical cases of typhoid therefore are fewer and milder among vaccinated persons. Does it follow that immunizations will reduce the incidence of typhoid carriers? Is an active case of typhoid necessary for development of the carrier state, or are persons likely to become carriers after having had subclinical infections?*

Hugh W. Randel, M.D., New York.

Answer.—Although typhoid vaccine has been extensively used for many years, direct epidemiologic evidence for its effectiveness in man has been, until recently, meager and of uncertain reliability. A recent, carefully controlled field study in Yugoslavia indicates that heat-killed phenolized vaccine offers substantial but incomplete protection against clinical typhoid fever. There is practically no information on whether vaccination will prevent development of the carrier state. A substantial number of chronic fecal or urinary carriers, when discovered through bacteriological surveys or through search for sources of infection in outbreaks or isolated cases in families, give no history of a recognized attack of typhoid fever in the past. There generally is no information whether they became carriers as a result of an undiagnosed clinical attack or of subclinical infection. It seems probable that vaccination will reduce the incidence of typhoid carriers, at least to the extent that it reduces incidence of the disease, but this opinion is not based on direct evidence.

SPONDYLOLISTHESIS

To the Editor:—*Please recommend treatment for an athletic young man, aged 18, who has a neural arch defect of the fifth lumbar vertebra with first-degree slipping on the sacrum. What are the findings regarding success of operation in such cases?* *G. K. Mahl, M.D., Ironton, Ohio.*

Answer.—Treatment of spondylolisthesis depends somewhat on its symptoms. If the patient described is having pain, probably surgical relief is advisable. If there are no symptoms and the defect was discovered incidentally, operation can be delayed until symptoms develop. There are two basic methods for surgical treatment of spondylolisthesis. One is to graft the bones posteriorly, immobilizing the loose segment between the stable segments above and below. In this patient, this would mean fusion of the fifth lumbar vertebra to the fourth and to the sacrum. Results with this method of treatment usually are good. There are published surveys of patients who have had this operation for spondylolisthesis. In rare instances, anterior fusion of the vertebral centrums is done.

The second type of operative procedure involves decompression of the nerve roots as they pass by the site of the opening in the pars interarticularis. According to more recent concepts of spondylolisthesis, this opening is a result of a fracture that has occurred in the pars interarticularis, with nonunion. Callus, cartilage, and other fibrous elements that form about the fracture encroach on the nerve root. Gill's operation consists of removing the loose neural arch posteriorly and thoroughly decompressing the nerve roots at the site of the pseudarthrosis in the pars interarticularis. This procedure has the added advantage of preventing the loose posterior segment from impinging on the cauda, as it might if it were caught and squeezed between the posterior elements of the fourth lumbar and first sacral vertebrae, especially on hyperextension. Results of the Gill operation are not yet fully known. There have been reports of incomplete relief of back pain. There should be no hesitancy, however, in recommending the traditional spinal fusion for this syndrome of spondylolisthesis in an 18-year-old boy with symptoms.

X-RAYS OF EXPECTANT MOTHERS

To the Editor:—*Many expectant mothers ask if a chest x-ray is injurious to the unborn baby. In the past, it has been considered wise to obtain routine chest x-rays of pregnant women. Is there any evidence indicating they are injurious to the fetus? Is the procedure considered worthwhile?*

Oliver E. H. Larson, M.D., Zumbrota, Minn.

Answer.—There is no evidence that very small doses of ionizing radiation, such as those associated with properly controlled chest roentgenography of the expectant mother, are injurious to a fetus. Moreover, many chest lesions occur in pregnant women which demand prompt diagnosis and treatment in the interests of both the mother and the unborn child. Since such lesions are frequently asymptomatic or produce symptoms easily attributable to the pregnancy, they are detected early only by

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

chest roentgenography. Therefore, it would appear worthwhile to obtain chest roentgenograms in pregnant women. It is preferable to defer such roentgenography until the second trimester of pregnancy, and it is the obligation of the radiologist to take every precaution to minimize the exposure associated with the study by proper selection of roentgenographic factors and materials and by proper filtration and diaphragm of the x-ray beam. To answer patients' questions concerning possible hazards of medical use of x-rays, the following facts may be helpful: First, excessive ionizing radiation may induce undesirable changes of two kinds in an organism: somatic changes in the person receiving radiation and genetic changes in the germ plasm of the person which may ultimately increase the number of undesirable mutations in the population. Second, while the tissues of the fetus are relatively more sensitive to the effect of radiation than adult tissues, particularly in the early weeks of fetal life, there is nevertheless a threshold dose of absorbed ionizing radiation below which somatic effects do not appear to occur. Properly controlled diagnostic x-ray studies of any type rarely, if ever, approach this threshold. Evidence based on studies in other species, however, indicates that there is no threshold for genetic effect. Third, any ionizing radiation absorbed by the germ plasm of the fetus or the mother is, therefore, theoretically undesirable in terms of the future population and should be minimized if possible. Of the many sources of ionizing radiation to which everyone is exposed (such as cosmic rays), the medical use of x-rays is the most readily controlled. Diagnostic x-ray exposure of human beings should be kept to the minimum consistent with good medical management. Thus, the proper use of diagnostic roentgenography becomes a matter of good medical judgment. Unnecessary radiation exposure should certainly be avoided, but, where there is any reasonable expectation that the patient may benefit from a roentgenographic study, it should not be deferred because of unfounded or exaggerated fears.

CARE OF AMPUTATION BELOW THE KNEE

To the Editor:—*Please give advice concerning care and hardening of the stump after an amputation below the knee and prior to fitting of prosthesis. The patient had this amputation approximately six weeks ago, and it is felt that physiotherapy should be started as soon as possible.*

Benjamin T. Strehlow, M.D., Bremerton, Wash.

Answer.—The question implies that there has been no therapy for the amputation during the six weeks after operation, and there is no description of the present condition of the amputation stump. The usual postoperative routine for amputation below the knee begins with active flexion and extension exercises as soon as decrease in pain permits, usually on the third or fourth day. The most important therapeutic principles are to maintain a free range of motion with powerful extension and to insure symmetrical shrinkage during the healing period. After primary healing and removal of the stitches, exercise in the whirlpool, with or without gentle massage to prevent adherent scarring, is often advisable. The contemporary opinion is against any specific measure directed toward hardening of a stump. Treatment is directed toward progressive strengthening of all functioning muscles and the prevention of adherent scars and adherent neuromas that may complicate use of the stump in a prosthesis. Between periods of active treatment, the stump should be properly bandaged with recurrent turns of an elastic bandage that does not cause constricting bands. With primary healing and no complications, most patients with such amputations are ready for measurement and fitting in six to eight weeks after the amputation. If therapy is to be started at six weeks after operation, it should include several periods of active resistance exercises each day with whirlpool and gentle massage under supervision, at least once daily. The stump should be carefully wrapped for proper shaping at all times when the patient is not receiving active treatment.

SCARLET FEVER DIAGNOSIS

To the Editor:—*A marked increase in incidence of scarlet fever has been reported in this area. Other than by clinical impression and throat culture, which only indicates a streptococcic infection, no definite means of confirming or disproving the diagnosis has been found. The "Shultz Carlton" reaction was formerly used, but no drug companies are making antitoxin or antiserums. Is there any other diagnostic aid? Recently, the Dick test has been done in persons with suspected cases early in the course of the disease and 10 to 14 days later. All tests have given positive results. In scarlet fever, should not findings on this test become negative during or shortly after convalescence? Would early effective doses of penicillin prevent progress of the disease and and thus interfere with development of immunity? How soon after the onset of scarlet fever does the result of the Dick test become negative?*

Harold J. Sargent, M.D., Newfoundland, N. J.

Answer.—At present, clinical scarlet fever is an extremely mild disease. During the past 20 years, there has been a sharp decline in both frequency and virulence of streptococcic infections. Now there is a rising incidence, but the disease is seldom severe. Satisfactory diagnosis is not always a simple matter. Although the Dicks maintained that a specific erythrogenic streptococcus is responsible for scarlet fever, Griffith in England reported 30 types of streptococci capable of producing the disease. For a number of years the New York State Health Department has not recognized scarlet fever as a separate entity but calls for the reporting of streptococcic infections "including scarlet fever." When scarlet fever thrived the result of the Dick test was usually negative 10 days or two weeks after onset of the disease, but this did not signify that the nose and throat were free of streptococci. A person with a negative response is not immune to streptococcic infection that may be acquired by contact with a patient with scarlet fever. Under such circumstances, a streptococcic sore throat may develop but there is no eruption on the body surface. A streptococcic infection does not confer lasting immunity. Erysipelas is an outstanding example. Although second attacks of clinical scarlet fever are rare, repetitions of streptococcic sore throats are not uncommon. Penicillin is of value in suppressing and eliminating streptococci. There is no method that will establish active immunity to streptococcic infections.

HEARING IMPAIRMENT

To the Editor:—*A 23-year-old woman with a congenital deviation of the nasal septum and a negative family history was affected by influenza at the age of 13. The onset was characterized by fever, dizziness, and earache on the right. During convalescence, she noticed bradyacusia on the right side. Four years later, examination revealed a 25% reduction in hearing on that side. Medical treatment was carried out intermittently, and neither symptoms nor further diminutions of hearing were experienced. The bradyacusia was attributed by three specialists to three different pathogeneses: otosclerosis, deviated nasal septum, and acute influenzal otitis. Could otosclerosis begin at the age of 13, have an acute onset, and be unilateral? Could it cause mild and nonprogressive bradyacusia for 10 years? What is the prognosis for hearing in early otosclerosis, a congenital deviation of the nasal septum, and an acute middle-ear otitis? Which genetic pattern does otosclerosis follow?*

Joseph Giardina, M.D., Brooklyn, N. Y.

Answer.—The history in this case is not adequate to permit a diagnosis. The question whether loss of hearing in the right ear is due to a lesion of the sound conduction apparatus or to the sense organ and/or nerve can be answered by routine hearing tests. This and other information is needed before an opinion can be given. Otosclerosis may begin at age 13. It may be unilateral but is bilateral in the great majority of patients. The onset may appear to be acute, the patient suddenly becoming aware of hearing loss during the course of acute infection, but acute onset is not characteristic. The disease usually progresses with more or less irregularity. Congenital deviation of the nasal septum is not known to have any influence on otosclerosis. Acute middle-ear inflammation may have an influence on otosclerosis, but reliable evidence is not available. The genetic pattern which otosclerosis may follow is not clear, because it is known that otosclerosis may be present without producing hearing impairment.

FETAL HEART SOUNDS

To the Editor:—*A stillborn fetus, weighing 9 lb. 14 oz. (4,479 Gm.), was recently delivered. It was thought that fetal heart sounds had been heard all through labor. Four experienced observers located what they felt sure were easily audible fetal heart sounds 2 in. to the right of the umbilicus. The placental bruit was in the left flank. On delivery, the fetus showed maceration over the anterior surface of the abdomen. How does one account for the fetal heart sounds? The mother, a registered nurse, said she felt life until she went into labor.* *M.D., New York.*

Answer.—For the obstetrician to be absolutely certain of the presence of fetal heart tones and the patient of fetal activity is at times most difficult. The finding of maceration of the fetus at the time of delivery would definitely prove intrauterine death and rule out the possible presence of fetal heart tones during labor. The only explanation is that there were apparently errors in interpretation of the presence of fetal heart tones and fetal activity.

ACHING AND TWITCHING IN LEGS

To the Editor:—*A patient, 64 years old, has complained for about a year and a half of aching and twitching sensations in both lower extremities, predominantly in the calves and ankles. It has been severe enough to keep him awake at night unless he is under heavy sedation with barbiturates. Normal dorsalis pedis, posterior tibial and femoral pulses are felt. There are short saphenous varicosities bilaterally, with venous stasis changes. When first seen, he had large eruptive stasis ulcers on both lower extremities. Tolazoline, 25 mg. four times a day, controlled these adequately but in no way reduced the disturbing sensation. He has since been given phenylbutazone, various corticosteroids, quinine, diphenhydramine, nicotinic acid, vitamin B_{12} injections, and, finally, Ace bandages, all with no relief. What further studies are indicated, and what additional therapy might be given?*

Leonard A. Winski, M.D., Millville, Pa.

Answer.—It is assumed that this patient's symptoms are unrelated to exercise or may even be improved on his moving about. Hence, they are not due to deficient arterial circulation, at least of the extremities. Nor would the postphlebitic syndrome, as manifested by short saphenous incompetence and stasis ulcer, be responsible for twitching of the calf muscles at night. The blood calcium level might be ascertained. A systematic neurological examination, directed toward motor, sensory, and reflex changes and including spinal puncture, should be considered. A roentgenographic study of the lumbosacral part of the spine might detect congenital or acquired structural deformities or calcification of lumbar arteries feeding the spinal cord. Any protective muscle spasms of the back and radiating pain on motions of the trunk should be noted. Only if all organic causes can be excluded should a functional origin of the symptoms be considered. Such a condition may be present for many years without progression. In fact, reassurance helps more than drug therapy. Self-medication must be discouraged.

DIAGNOSIS OF LEPROSY

To the Editor:—*A woman, aged 32, apparently has leprosy involving the left peroneal nerve. The patient has already experienced spontaneous amputations of all toes on that foot and has complete anesthesia of the anterior portion of the foot. No indurated nerve branches can be felt. The patient gives a history of having had this trouble since she was 5 years of age. How much leprosy is there in the Midwest? What is the best form of treatment? What epidemiological factors must be considered? What is the best way of making an accurate laboratory diagnosis?*

S. W. Scorse, M.D., Joplin, Mo.

Answer.—During the period 1921 through 1958, the following number of patients were admitted to the Public Health Service Hospital at Carville, La., from the Midwest: Illinois, 35; Minnesota, 9; Iowa, 3; Missouri, 11; Kansas, 5; Ohio, 13; Wisconsin, 4; Indiana, 10; and Nebraska, 2.

Missouri's 11 cases were distributed as follows: Essex, one patient admitted in 1925; Independence, one admitted in 1927; Kansas City, two admitted in 1926; St. Louis, six admitted in 1922, 1927, 1932, and 1940; and Winfield, one admitted in 1950. Sulfones, in the form of sulfoxone sodium, glucosulfone sodium, or diaminodiphenylsulfone, are the best treatment available today. Residential history gives more factual suggestive evidence than family history. The disease is endemic in Texas, Louisiana, Florida, and California. Residence abroad in China, Japan, South America, Mexico, or Africa would be of considerable significance. All household contacts and relatives who have had close and prolonged contact with the patient suspected of having the disease should be examined for nerve or skin lesions. Skin smears stained by Ziehl-Neelsen method should be examined for acid-fast bacilli. Biopsy from the affected area should be sent to the U. S. Public Health Service Hospital at Carville and/or the Armed Forces Institute of Pathology, Washington 25, D. C., for examination by competent pathologists who are familiar with the histopathology of leprosy.

SKIN CANCER SUSCEPTIBILITY

To the Editor:—*A light-complexioned man, aged 29, has had numerous keratoses on the face and arms, with several proved to be cancerous. It is necessary for him to work out of doors. He has been instructed to wear a broad-brimmed hat. What kind of ointment or protective lotions might be prescribed? Is there available any sun-screening ointment that contains antimalarial drugs?*

M.D., Alabama.

Answer.—The ingredients of sun screens are chosen for their ability to absorb ultraviolet energy with wave lengths ranging particularly from 2,540 to 2,970 A., for these are the rays most concerned with the production of erythema. Yellow petrolatum used alone has significant sun-screening value. No lotion is likely to protect so well as a thick ointment. The usual ingredients of sun-screening preparations are homomenthol salicylate, menthol anthranilate, digalloyl trioleate, and various derivatives of para-aminobenzoic acid. Incorporation of zinc oxide, titanium dioxide, or bentonite will increase the opacity of the ointment. The fishing guides of the Texas Gulf Coast often use zinc oxide paste and dust talc over it generously. Unexpected blistering reactions occasionally follow contact with para-aminobenzoic acid derivatives, presumably representing cross-sensitivity. Photosensitization by contact occurs occasionally from digalloyl trioleate. Ointments containing homomenthol salicylate or anthranilate with added zinc oxide or titanium dioxide may be recommended. These are available commercially. Sun-screening preparations with antimalarial drugs seem to have received no mention in the literature, but experiments with them should be easy to design. There is no reason to expect them to be superior. That this patient has to work out of doors is open to argument. Aggravation by sunlight of cancer in the susceptible skin of some persons should be avoided at any cost.

TEACHING DEAF CHILDREN

To the Editor:—*Is there a program or textbook of directions which would be helpful to parents of a 3-year-old girl who is apparently completely deaf? She does not talk but seems mentally capable otherwise. It is hoped to teach the parents to help the child phonate sounds and develop as much voice for talking as possible.*

M.D., Montana.

Answer.—There is much fine material available for the parents of deaf children. A particularly good booklet is the one entitled "If You Have a

Deaf Child," a collection of helpful hints and useful information for parents of pre-school-aged deaf children, published for the Illinois Annual School for Mothers of Deaf Children by the University of Illinois Press, Urbana. Information about the Annual School may be obtained from the Division of Special Education, Office of the State Superintendent of Public Instruction, Springfield, Ill. The "Correspondence Course for Parents of Little Deaf Children," developed by Mrs. Spencer Tracy and obtainable from the John Tracy Clinic, 806 W. Adams Blvd., Los Angeles 7, has won widespread acceptance and is particularly valuable in helping parents stimulate the deaf child to speak. A number of pamphlets may be obtained from the Alexander Graham Bell Association for the Deaf, Volta Bureau, 1537 35th St. N. W., Washington 7, D. C. This organization has a parent section which represents 23 parent groups and more than 800 sets of parents throughout the United States who find that working together on their common problems brings many benefits.

PAINFUL PURPURIC DERMATITIS

To the Editor:—*A 24-year-old woman, with no previous serious illness, three months ago developed a painful purpuric dermatitis limited to left lower part of the abdomen and left gluteal area. Since then, she has had recurrent episodes on the left side of the face, left arm, and dorsum of the left hand. Skin biopsy showed no pathology in epidermis and a perivascular infiltrate. Chest x-ray, platelet count, and blood cell count are normal, as is the urine. There is no joint or abdominal pain. What might be the cause, and what treatment should be given?*

M.D., Georgia.

Answer.—The information in the query is inadequate to permit a diagnosis. It would be desirable to know the character of the perivascular infiltrate. Was Perls' test done to ascertain whether hemosiderin was present? What were the results of the Rumpel-Leede test? What was the coagulation time, bleeding time, prothrombin time, and albumin-globulin ratio? Had the patient taken any drugs that could have produced purpura? Thrombocytopenic purpura can be ruled out because of the normal platelet count. There are various nonspecific factors which might conceivably lead to unilateral distribution of purpura, including a preceding contact dermatitis or pressure or trauma limited to one side of the body. A nonthrombocytopenic form of purpura with unilateral distribution would be most unusual. Pain in purpura is also most unusual. The question arises as to whether this patient really had purpura or has some other condition such as a vascular nevus with segmental distribution.

PERSISTENT SCALP FOLLICULITIS

To the Editor:—*A man, aged 35, has had intractable furunculosis of the scalp for 10 years. The patient relates this to earlier furunculosis of the buttocks which improved after a few years. He has received a variety of antibiotics and all the x-ray therapy to the scalp that is considered advisable. Careful attention has been given to cleanliness, and he scrubs with hexachlorophene daily. Please give advice on this problem.*

Benjamin T. Strehlow, M.D., Bremerton, Wash.

Answer.—From the description, it sounds as though this patient is suffering from perifolliculitis capitis abscedens et suffodiens, also called dissecting cellulitis of the scalp. This condition is notoriously resistant to therapy. X-radiation is successful at times, but the dosage must be adequate to produce a temporary epilation. Surgical approaches include wide marsupialization with or without grafting. While this procedure produces scars, the condition is basically a scarring one itself. Incision and drainage of abscesses aid in their resolution. Of conservative measures, corticosteroid therapy offers greatest hope. Triamcinolone, 4 mg. four times a day by mouth, could be given and the dosage increased or decreased as indicated by therapeutic results. However, long continuation of this therapy must be anticipated. Use of broad-spectrum antibiotics, given concurrently with the corticosteroids, is theoretically desirable. Vaccines (such as stock staphylococcus toxoid) are indicated. Locally, wet dressings (especially Alibour water) and antiseptic ointments (5% ammoniated mercury) and/or antibiotic ointments may be helpful. Probably this condition is related, at least therapeutically, to hidradenitis suppurativa of the axillae, groins, and buttocks.

USE OF DEPILATORIES

To the Editor:—*It is recognized that considerable risk is attached to the indiscriminate use of depilatories. Please give information in regard to the product Pellex and to any possible deleterious effects which might follow its use.*

D.A. MacGregor, M.D., Wheeling, W. Va.

Answer.—Products of this type ordinarily contain calcium thioglycollate as their active chemical. This is the same chemical found in cold-waving preparations. In these cosmetics, the concentration of the thioglycollate and the pH of the solution are regulated so that the hair is softened to facilitate giving it a new configuration. In chemical depilatories, these properties are regulated so that the hair will be destroyed. In view of the similarity between the chemical composition of the hair and skin, a preparation that is effective in destroying hair may be irritating to the skin. There is apparently no reason to suspect that this chemical is absorbed through the skin. Any unfavorable reactions which occur will be local and most often take the form of skin irritation. If the product is used, it is advisable that the caution statement on the package be observed carefully. Also, the test area to which it is first applied should be not the face but rather the arm or leg. If no unusual irritation occurs, it is wise to apply the depilatory to a small area of the face initially. If this is satisfactory, then it may be applied to a larger surface. If at any time with repeated use a skin reaction occurs, future use is contraindicated.

SPLENIC ARTERY ANEURYSM

To the Editor:—*A patient, aged 37, has a splenic artery aneurysm, diagnosed by x-ray evidence of calcification in the left upper abdominal quadrant. The surgical literature recommends splenectomy for splenic artery aneurysm, but the radiologist says this condition is quite common in older people and he feels that ignoring it would impose no risk. He considers splenectomy to be an unnecessarily radical procedure in this case. How frequently is accidental diagnosis made of splenic artery aneurysm? Should this condition be ignored?* *M.D., California.*

Answer.—Calcification associated with splenic arterial aneurysm is seen fairly frequently in gastrointestinal x-ray series. Most roentgenologists regard it as being relatively benign. In older persons, it is not considered to warrant splenectomy unless there are symptoms or evidence from repeated studies of aneurysm enlargement. Many are observed over a period of years without change. Recently there has been increased interest on the part of surgeons in performing splenectomy for this condition. More careful studies of the future course of patients who do not have a splenectomy compared with those who do are essential before a definitive answer can be given regarding the indications for operation. In such figures, the mortality from the operative procedure must be included. To the knowledge of this consultant, valid figures of controlled series clarifying this point are not yet available.

COLD WAVE LOTIONS

To the Editor:—*Are there any known or proved allergic reactions to cold wave lotions used by beauticians directly or indirectly for permanent waving? Might certain effects appear after a number of years?* *M.D., Pennsylvania.*

Answer.—When cold wave solutions were first introduced on the market, there was some indication that they might be potential health hazards. However, subsequent investigations indicated that they are safe to use if directions are followed carefully. They are generally considered to have a low index of sensitivity. A significant study was carried out by the Food and Drug Administration over a period of two years on 10 widely used cold wave solutions (Draize and others, Percutaneous Toxicity of Thioglycollates, *Proceedings of the Scientific Section, Toilet Goods Association,* May 16, 1947, page 29). Their conclusions were as follows:

"The majority of complaints of both patrons and operators are probably due to misuse of the products or failure to heed proper directions and precautions. Except in the case of sensitive individuals, the judicious use of these solutions should prove a relatively innocuous procedure.

"In the case of the operators who may be exposed daily to varying amounts of the waving solution, it is believed that protection for their hands is essential."

SODIUM IN INSTANT COFFEE

To the Editor:—*Do instant coffees have a high sodium content? Is it high enough to warrant elimination from low-sodium diets?*

F. L. Troost, M.D., Holt, Mich.

Answer.—According to the National Food and Nutrition Board of the National Research Council, instant coffees have an average sodium content of about 84 mg. per 100 Gm. of the dry product. A cup of coffee made from such products would contain about 4 mg. of sodium. It would therefore be the opinion of this consultant that instant coffee could be incorporated in a low-sodium diet.

PROFUSE SWEATS IN PATIENT WITH DIABETES

To the Editor:—*A 66-year-old diabetic is having attacks of profuse sweating at intervals of between two to five days. They last several hours. He had coronary thrombosis in 1955, from which he made a good recovery, and has moderately advanced arteriosclerosis. The blood sugar level averages 160 to 200 mg.%. When the blood sugar level goes below 160 mg.%, the attacks are just as severe and frequent. When insulin dosage is increased, attacks seem to become worse. The patient has moderate hypertension (180/80 mm. Hg), is 5 ft. 5 in. (165.1 cm.) tall, and weighs 130 lb. (59 kg.). The attacks make him feel weak. Fever is not observed. He is receiving 10 units of regular insulin twice a day and is on a 1,500-calorie diet.*

Franklin L. Wilbur, M.D., Asbury Park, N. J.

Answer.—It is quite possible that this patient's attacks of sweating are due to hypoglycemia. Evidence that would either support or exclude this possibility could be obtained by determining the blood sugar level three or four hours after the injection of insulin or, better still, during an attack of sweating. It is unusual for patients of this age to require two doses of regular insulin daily. A trial with 10 or 15 units of one of the intermediate-acting insulins (NPH or lente) given as a single morning injection would be worthwhile.

SPONTANEOUS ACETONURIA

To the Editor:—*A normally active, well-developed, well-nourished 3-year-old boy on occasions has had a fruity breath. Examination of the urine for acetone with the standard powder has shown a strong positive reaction on these occasions. Evaluation of sugar in the urine has always given negative results. The child has never been manifestly ill. The family history is negative for diabetes. What additional studies are indicated in this child? What is the most likely cause of these findings?* *M.D., New York.*

Answer.—The most likely diagnosis in this patient is starvation. Either the child does not take any food for some hours or he vomits, with resulting acetonuria. This would not be abnormal for a young child, for acetonuria appears easily in childhood. The child might have abnormality of glycogen metabolism, with appearance of acetone because glycogen is not available. But this is relatively rare, and, inasmuch as this boy is said to be well, it may be assumed that this is a feeding problem. Spontaneous acetonuria has been reported from Europe, but not much of it is seen in America. Such spontaneous acetonuria is said to occur only in childhood and gradually disappears without treatment as the child gets older. It does not appear to be a serious manifestation.

LIPSTICK CHEILITIS

To the Editor:—*A patient has tried many different types of commercially available lipstick, all of which produce marked blistering and allergic reaction. What ingredients would cause this reaction? Are there any lipsticks this patient could use?* *F. C. Buffington, M.D., Norman, Okla.*

Answer.—Cheilitis caused by lipstick is not uncommon. The staining dyes used in many lipsticks—eosin dyes or halogen derivatives of fluorescein—are believed to be rather frequent photosensitizers. There are available lipsticks which do not contain eosin dyes, but these are nonindelible and their lasting powers are minimal. They must be requested specifically, inasmuch as most manufacturers of hypoallergenic cosmetics also sell an indelible lipstick with a low concentration of eosin.

Other ingredients ordinarily found in lipsticks are relatively innocuous. They contain a blend of oils, fats, waxes, and perfumes. The fats used may be cocoa butter, hydrogenated vegetable oils, lard, cetyl alcohol, or others. The oils are castor oil, peanut oil, soy bean oil, or other vegetable oils. The waxes used are beeswax, carnauba wax, or spermaceti, as well as mineral waxes, ceresin, and ozokerite. Dyes and lakes are added to the lipstick to provide color. These must come from lots approved by the Food and Drug Administration.

PREDNISONE IN ULCERATIVE COLITIS

To the Editor:—*A man, aged 25, has responded satisfactorily to prednisone, 15 mg. daily, for ulcerative colitis. He has been taking this dosage for approximately three years. During this period he has improved psychologically to the point where he has succeeded in working full time and has made a happy marriage. Is it desirable to reduce the dosage gradually with a view to withdrawing prednisone therapy entirely? What is the present opinion regarding the period of withdrawal? What is the justification for continuing the present therapy without attempting withdrawal?* *M.D., New York.*

Answer.—Three years of continued steroid therapy for ulcerative colitis would seem to be an unusually long time. To discuss future therapy satisfactorily, it would be necessary to know the nature of the patient's colitis, the severity of his illness, the extent of intestinal involvement, and the nature and amount of disability produced. However, it can be said unequivocally that the prednisone dosage should be gradually reduced with a view to discontinuing this therapy entirely. Since he has taken the drug for such a long time, it is suggested the withdrawal period cover at least six or eight weeks.

TEST FOR PHENYLPYRUVIC ACID

To the Editor:—*What is the easiest way to test for phenylpyruvic oligophrenia?* *M.D., Florida.*

Answer.—Phenylpyruvic oligophrenia is a hereditary form of mental abnormality characterized by the excretion of phenylpyruvic acid in the urine and associated with a severe degree of mental retardation. Frequently muscular rigidity, tremor, and ataxia are present. Convulsions may also occur. The chemical defect of such patients is inability to oxidize adequate amounts of phenylalanine into tyrosine. This in turn leads to production of increased amounts of other metabolic end-products. One of these is phenylpyruvic acid, which usually appears in the urine if the level of phenylalanine in the blood serum exceeds 20 mg.%. This substance is usually detected in acidified urine by adding a few drops of a 5% solution of ferric chloride. A characteristic dark green color appears with a minute or two and then, after a time, disappears. Recently, Baird (*J. Pediat.* 52:715, 1958) reported a quicker and, in his opinion, more reliable test. A paper stick is impregnated with ferric chloride and glacial acetic acid and allowed to dry. A positive reaction is said to have occurred if the chemically treated portion of the stick turns green, gray, or dark blue within 60 seconds of its immersion in the urine.

INTERNAL TREATMENT OF WARTS

To the Editor:—*During discussion with a local druggist of a news magazine announcement about a pill to remove warts, he mentioned a proprietary preparation of methionine in tablet form for internal use against warts. Please give information on this. Would such treatment help remove the mild, painless skin growths so common on the faces of aged persons?*

Mary B. Sanford, M.D., Methuen, Mass.

Answer.—This consultant has not been able to find any information on internal treatment for warts, nor has the announcement mentioned been seen. It has been stated (Merck Manual of Diagnosis and Therapy, edited by Lyght and others, ed. 9, Rahway, N. J., Merck & Co., Inc., 1956 p. 1605) that systemic treatment of warts "probably is of little or no value apart from its problematic psychologic effect." The well-known essential amino acid, methionine, is marketed in various forms. Its use as an adjunct in the treatment of liver disease is mentioned in "New and Nonofficial Drugs" (Philadelphia, J. B. Lippincott Company, 1959, p. 636), but no record is found of its promotion as an internal treatment for warts.

WHAT'S IT GOING TO BE, DOCTOR?

To the Editor:—*After a woman bears two, three, or four consecutive children of the same sex, what are her chances of bearing a child of the opposite sex in her next pregnancy? What factors other than chance are operating?*

Arthur J. Barnett, M.D., Monahans, Texas.

Answer.—At each pregnancy there is a 50% chance of producing a child of either sex regardless of the previous children's sexes. After four children of the same sex, the chance is still equal that a child of the opposite sex will be born the next time. The situation is the same as in tossing a penny; there may often be a run of heads, but the chance is still 50% of getting tails at the next toss. National statistics show a slightly greater number of boys born, but this can be ignored for all practical purposes.

IRIDOLOGY

To the Editor:—*Please give information on iridology. The practice consists of diagnosing various body ailments by visual inspection of the iris.*

J. D. Losey, M.D., College Place, Wash.

Answer.—This procedure is of European origin and has been accepted by chiropractors, naturopaths, and similar cultists for a good many years. The story goes that a Hungarian had a pet owl, and that as he was looking into the eyes of the owl he accidentally broke its leg. When the bone snapped, a spot appeared on the iris of the owl's eye. The discoverer of this alleged phenomenon was said to have been 7 years old at the time. Later he studied medicine and, remembering his experience, began to gaze into the eyes of his patients. Books and charts and other material have been prepared on this subject. It goes hand in hand with spinal adjustment as the preferred method of "cure."

BONE HEALING MISINFORMATION

To the Editor:—*A nonmedical unofficial source states that fractured bones will not heal in the Aleutians. Is this true?* *M.D., South Carolina.*

Answer.—The Aleuts are native to the Aleutian Islands and were the only residents of the Aleutian peninsula prior to explorations of the Russians. Now the population is made up of pure-blooded Aleuts, some half-breeds, and, of course, Caucasians who live in the area. The bone physiology of the Aleuts is no different than that of the Eskimos farther north or the Indians in the interior. A practitioner in Alaska has never seen or heard of a case of bony nonunion in natives or Caucasians who have lived in the Aleutians. The same factors that may produce delayed union and nonunion govern healing here.

STERILIZING THERMOMETERS

To the Editor:—*Please give instructions for sterilizing thermometers, oral and rectal, used daily in general practice. What methods are considered adequate?*

Erwin Steinman, M.D., Washington, D. C.

Answer.—Disinfection of clinical thermometers, oral and rectal, may be accomplished by storage in ethyl or isopropyl alcohol, approximately 85% by volume, in a matter of minutes, providing gross contaminants of mucus and feces have been removed. A longer exposure interval is required if tubercle bacilli are among the bacterial contaminants. The solution should be changed frequently enough to keep the concentration in the effective range.

Government Workers' Health Insurance . .
New Housing Bill . .
Joint Council on Aged Meets . .

HEW APPROPRIATIONS TO WHITE HOUSE

Congress completed action on a 3.9-billion-dollar appropriations measure for the Labor Department and the Department of Health, Education, and Welfare and sent the legislation to the President's desk. The bill carried more funds than originally approved by the House but less than a Senate version. However, the total was still 260 million dollars more than the administration had requested, with the bulk of the increase being for health research and hospital construction.

The National Institutes of Health, a branch of the HEW's Public Health Service, received 400 million dollars for its medical research activities, 105 million dollars more than sought by the administration.

The lawmakers approved $186,200,000 for the federal Hill-Burton program of providing grants to states for hospital construction, with the states matching the federal outlays. This was 85 million dollars over the budget figure.

Here is what the various institutes that make up the National Institutes of Health received under the bill:

General Research and Service, $45,900,000; Cancer, $91,200,000; Mental Health, 68 million dollars; Heart, $62,200,000; Dental, 10 million dollars; Arthritis, $46,800,000; Allergy, 34 million dollars, and Neurology, $41,500,000.

CONCLUDE HEARINGS ON PROBLEMS OF AGED

The special Senate labor subcommittee looking into problems of the aged wound up a series of fact-finding sessions here and made plans for hearings in various cities of the country this fall.

The subcommittee, headed by Sen. Pat McNamara (D., Mich.), heard administration officials and spokesmen for national organizations outline their activities.

Testifying for the American Medical Association was Dr. Frederick C. Swartz, Chairman of the A. M. A.'s Committee on Aging. He declared that "solutions are being found, that real progress is now being made through the cooperative efforts of private citizens."

"At this time," he said, "retirement villages, new nursing homes, chronic-disease care centers, home-care programs, recreational facilities, and research projects are being set up from coast to coast—and in substantial number. Furthermore, many, many more are on the way."

Dr. Swartz testified that compulsory retirement ages have much to do with health; he said he has seen many cases in which lack of useful activity has caused older persons to suffer psychologically and physically. "Personnel policies should be flexible enough . . . to use the yardstick of ability instead of the yardstick of age," he said.

Noting that each year more and more of the Americans who are reaching the age of 65 are covered by private, voluntary health insurance, Dr. Swartz said "the problem of financing health services for the aged is therefore a temporary, not a permanent one."

The percentage of senior citizens who need and want health insurance will increase until three-quarters will be covered in 1965 and 90% in 1970, he testified.

Other witnesses, including spokesmen for the Communications Workers of America and the United Steelworkers, also spoke against compulsory retirement ages. Senator McNamara declared that older persons should be included in the main stream of social and economic life.

POLIOMYELITIS INCIDENCE CONTINUES HIGH

The Public Health Service reported that cases of poliomyelitis were continuing to run much higher than last year but that the steep rise during the week ending July 18 appeared to have slackened. For the week ending July 25, 278 cases, including 177 paralytic cases, were listed. This compared with 257 cases in the previous week, of which 166 were paralytic.

For the latest period only the middle Atlantic states showed a sharp rise, due to widely distributed cases in Pennsylvania. PHS said clusters of cases were appearing throughout the country, with no signs of a new epidemic such as occurred in Des Moines, Iowa, and Kansas City, Mo., earlier this year. In contrast to last year, the service said, cases are occurring not only in slum areas but in other districts as well, notably two outbreaks focused around military reservations in North Carolina.

(Continued on next page)

Through the 29th week of 1959 the cumulative total was 1,740 cases, with 1,133 paralytic. Last year the comparable total was 912 total cases. States having highest incidence of poliomyelitis were listed as Iowa, Missouri, Alabama, Texas, Arkansas, South Dakota, and Oklahoma.

HOUSE HEARINGS ON FEDERAL EMPLOYEES' HEALTH BILL

The House Post Office and Civil Service Committee was scheduled to wind up hearings this month (August) on the measure to provide private, voluntary health insurance coverage to the federal government's civilian personnel. Most interested organizations, including the American Medical Association, endorsed the principles of the legislation that won top-heavy approval in the Senate earlier this year.

Administration witnesses also backed the objectives of the legislation, but recommended that the proposed government share of the cost—one-half—be trimmed to one-third, with the employees paying two-thirds. However, the Committee was not expected to change the 50-50 ratio contained in the measure. The program would cost the government about 150 million dollars a year, compared with the 105-million-dollar cost the administration recommended.

The Senate bill does not offer coverage to employees who have already retired, a provision that the A. M. A. has recommended. This is a question of timing, and there is no telling now when these bills will be introduced.

NEW HOUSING BILL CONTAINS NURSING-HOME AID

A Senate banking subcommittee approved new housing legislation that includes some concessions to the protests made by President Eisenhower when he vetoed the housing bill that cleared Congress earlier this session. The new measure, like the old, provides for loan guarantees by the Federal Housing Administration of up to 75% of the cost of proprietary nursing homes.

Also retained in the latest bill were provisions for direct loan authorizations of 25 million dollars for interns' and nurses' housing under the college housing program, cut from $62,500,000 in the vetoed bill, and a 50-million-dollar revolving fund for direct loans to help private nonprofit corporations construct rental housing for the elderly. President Eisenhower objected to the latter provision.

Despite the elimination of some provisions criticized by President Eisenhower, the subcommittee bill calls for almost as much spending as did the original 1.4-billion-dollar measure.

INTERNATIONAL RESEARCH BILL

The administration asked the House to revise a Senate-passed measure establishing a 50-million-dollar program for international research cooperation. Testifying before a House commerce subcommittee, Arthur S. Flemming, Secretary of Health, Education, and Welfare, endorsed the objective of the legislation.

However, he urged that the President, rather than HEW, have direct responsibility for the program, recommended removal of the requirement for a new National Institute of Health, and asked deletion of the 50-million-dollar annual authorization. He said the program should come directly under the President, so it could be coordinated with foreign policy.

The bill would provide a 19-member advisory council with control over financial grants and authorize grants to the World Health Organization and other international groups for research and research training. It contains a specific prohibition against supporting operational public health or medical care programs abroad.

PRESIDENT WELCOMES JOINT COUNCIL SUPPORT

President Eisenhower, in a statement to the Joint Council to Improve the Health Care of the Aged, said the organization's pledge of support to the forthcoming White House Conference on the Aging "is most welcome." The 1961 conference, the chief executive declared, "will require a national effort if it is to achieve its objectives of providing programs to develop the full potential of our older citizens, enabling them to lead useful lives."

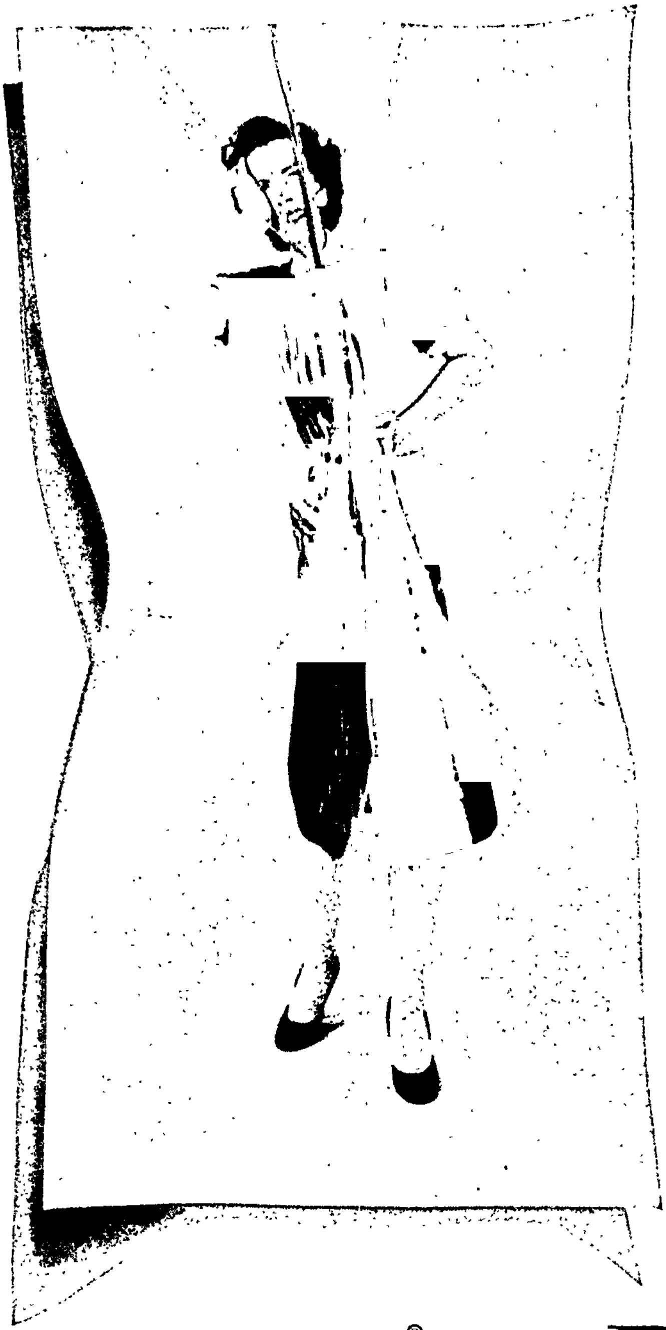
The joint council, which held its first official meeting here recently, is made up of representatives from the American Medical Association, the American Hospital Association, the American Dental Association, and the American Nursing Home Federation.

Dr. F. J. L. Blasingame, A. M. A. Executive Vice-president, declared that "with 9% of the nation's population now over 65, this first national conference is significant proof that the physicians of this country, along with hospital personnel, women's organizations, dentists, nurses, religious and labor leaders, industry, and government, are earnestly trying to achieve something worthwhile for America's senior citizens.

"One of our most immediate and compelling challenges is the health care of the aged," he said. "All of us must accept our full share of responsibility in solving the medical socioeconomic issues raised by the ever-increasing number of senior citizens."

At the conclusion of the two-day meeting, attended by 500 persons, representatives of the four sponsoring organizations declared that they are "unequivocally opposed to compulsory government health insurance for any segment of the population."

In smooth muscle spasm...



• controls *stress*

• relieves *distress*

Pro-Banthīne® with Dartal®

Pro-Banthīne—
unexcelled for relief of cholinergic spasm—
has been combined with
Dartal—
new, well-tolerated agent for stabilizing emotions—
to provide you with
Pro-Banthīne with Dartal—
for more specific control of functional gastrointestinal disorders, especially those aggravated by emotional tension.

Specific Clinical Applications: Functional gastrointestinal disturbances, pylorospasm, peptic ulcer, gastritis, spastic colon (irritable bowel), biliary dyskinesia.

Dosage: One tablet three times a day.

Availability: Aqua-colored tablets containing 15 mg. of Pro-Banthīne (brand of propantheline bromide) and 5 mg. of Dartal (brand of thiopropazate dihydrochloride). G. D. Searle & Co., Chicago 80, Illinois. Research in the Service of Medicine.

STEROID THERAPY AND TUBERCULOSIS

Harry Shubin, M.D., Robert E. Lambert, M.D., Charles A. Heiken, M.D., Adil Sokmensuer, M.D.
and
Allen Glaskin, M.D., Philadelphia

The effect of steroid therapy was investigated in 36 patients with acute and 107 patients with chronic forms of tuberculosis. The steroid used, prednisolone, was added to the regular regimen of streptomycin, isoniazid, and para-aminosalicylic acid. It was started at 50 mg. in divided doses for the 1st day and gradually reduced to 15 mg. by the 23rd day. Two case histories illustrate the recoveries seen in patients with the acute tuberculosis; there frequently was rapid objective improvement, and 32 patients recovered, including 8 with tuberculous meningitis. Two further case histories illustrate the striking results in chronic tuberculosis. The group of 107 included 20 patients who had been expected to die, and 15 of these recovered. The beneficial use of corticosteroids in the treatment of many diseases is well accepted, but the fact that it can reactivate tuberculosis is ofttimes overlooked. A typical case history illustrates such reactivation during treatment of lupus erythematosus with corticosteroids.

PROGRESS in medicine throughout the world has been greater during the past 20 years than in any other period. The discovery of penicillin was closely followed by the isolation of streptomycin, which opened a new era of chemotherapy in infectious diseases. The use of para-aminosalicylic acid (PAS) and isoniazid with streptomycin allowed us, for the first time, to effectively treat tuberculosis. Although the decrease in the death rate from tuberculosis has been marked, many serious problems must be solved if we hope to eradicate this disease.

Within the past 10 years, another distinct advance in medicine was established. This involved the corticosteroid drugs and their relationship to the "stress mechanism," inflammatory and allergic reactions. Their clinical effects in rheumatoid arthritis,[1] lupus erythematosus, and allergic manifestations including bronchial asthma have been well established.

Our interest in the corticosteroids began in 1954, as adjunct therapy in tuberculosis. Fully realizing that laboratory reports[2] showed reactivation of latent tuberculosis by these drugs, our first studies were on terminal cases. Since many of these patients had consistently low 17-ketosteroid levels, it was felt that a state of adrenal insufficiency existed,

Read before the Fifth International Congress on Diseases of the Chest, Tokyo, Sept. 11, 1958.

either acute or chronic. Therefore, replacement therapy with corticosteroids seemed indicated. When these preliminary findings proved impressive,[3] expanded studies were made with many similar good results.[4] Our early studies indicated the dangers of steroids when the patient had drug-resistant organisms with rapid spread, so that patients' conditions were thoroughly evaluated before treatment was given.

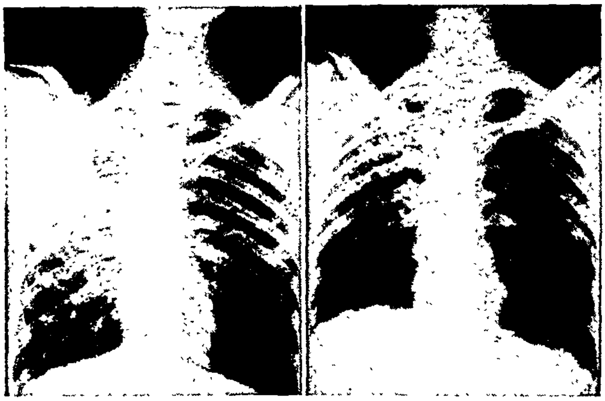

Fig. 1 (case 1).—Roentgenograms taken before prednisolone therapy was started (*left*, Nov. 8, 1957) and after 27 days of therapy (*right*, Dec. 5, 1957), showing extensive clearing of tuberculous lesions.

During this study, we also became increasingly concerned with the reactivation of latent or unrecognized tuberculosis in patients receiving steroids for nontuberculous diseases.[5] Although this number is relatively small in proportion to that of the general use of steroids, these patients are seen with increased frequency by chest specialists and physicians in other fields of medicine should be aware of this possibility.

Plan of Study

This report is concerned with the use of steroids in tuberculosis and their abuse when tuberculosis is reactivated after they are given in treatment of other diseases. The first group consisted of 36 patients with acute forms of tuberculosis, including miliary (14), meningeal (11), pneumococcic (9), and glandular (2), and a total of 107 patients with chronic disease (many with controls)—20 with terminal disease, 21 with allergic reactions to streptomycin or isoniazid, and 66 with pulmonary tuberculosis, moderately or far advanced, who were no longer responding to chemotherapy. We also included six patients with proved sarcoidosis (Boeck's sarcoid) and pulmonary involvement.

Evaluations before and during treatment included physical examinations, routine x-rays monthly, routine blood cell counts, blood chemistry, urinalysis, and determination of 17-ketosteroid level. The latter, together with electrolyte studies, glucose tolerance tests, and the Thorn test, is not now done routinely but only when indicated. Dosage, as in previous reports,[4c] usually was started at 50 mg. of prednisolone (Sterane) in divided doses for the 1st day and was gradually reduced to 15 mg. by the 23rd day.

Acute Tuberculosis

There were 4 deaths in the group of 36 patients with acute tuberculosis. One of these patients was proved at autopsy to have encephalitis, while the other three died shortly after admission (one with staphylococcic pneumonia, one, within 24 hours, with pneumonic tuberculosis, and one, within 72 hours, with meningeal tuberculosis), before adequate therapy could be given. Of the remaining 32 patients, in 14 with miliary tuberculosis and 4 with early meningitis toxicity disappeared within 48 hours, rapid clearing was seen on x-ray examination, and no residual complications occurred. Eight patients with tuberculous meningitis had an excellent recovery, and eight patients with tuberculous pneumonia showed rapid clearing. Two young girls with acute, toxic, tuberculous, cervical lymphadenitis showed almost complete resolution within 10 days after steroid treatment and chemotherapy were started and did not require operation. All patients received streptomyclidene isonicotinyl hydrazine sulfate (Streptohydrazid), streptoduocin (Distrycin), streptomycin, PAS, and/or isoniazid in addition to prednisolone. The following case histories are typical of patients in this group.

Case 1.—A 25-year-old man (fig. 1) was admitted to one of our hospitals on Nov. 7, 1957, with a diagnosis of acute tuberculous pneumonia involving two-thirds of his right lung with bronchogenic spread to his left lung. Toxicity was noted, and a sputum culture was highly positive for acid-fast bacilli. Triple drug therapy (streptomycin, isoniazid, and PAS) was started, but there was no improvement after eight days. Prednisolone therapy was started on Nov. 16, 1957, and marked clinical improvement and extensive clearing, seen on x-ray, occurred in 19 days (fig. 1). Prednisolone therapy was discontinued on Jan. 16, 1958, after the dosage had been gradually reduced, and at this time he had gained 22 lb. (10 kg.) and sputum cultures were negative.

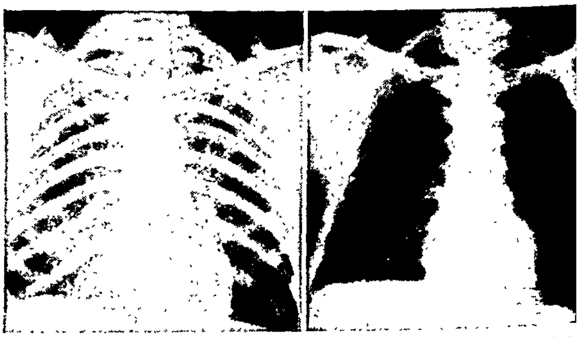

Fig. 2 (case 2).—Roentgenograms taken before prednisolone therapy was started (*left*, Sept. 30, 1957) and after three and one-half months of therapy (*right*, March 17, 1958), showing complete clearing of miliary tuberculosis.

CASE 2.—A 30-year-old man was hospitalized on Sept. 29, 1957, with diagnosis of miliary tuberculosis. His sputum was positive for acid-fast bacilli. He was placed on therapy with the three drugs (including 1,200 mg. of isoniazid daily). There was only slight improvement after two months of therapy. On Nov. 27, 1957, prednisolone was added to this regimen, and marked clearing on x-ray and definite clinical improvement occurred. Sputum cultures became and remained negative. Prednisolone was withdrawn on Feb. 13, 1958, and by March 17, 1958, there was complete clearing of his miliary tuberculosis (fig. 2).

Chronic Tuberculosis

A group of 107 patients had chronic pulmonary tuberculosis moderately or far advanced, and these cases were divided into three classes: (1) terminal, (2) allergic, and (3) active with no response to drugs.

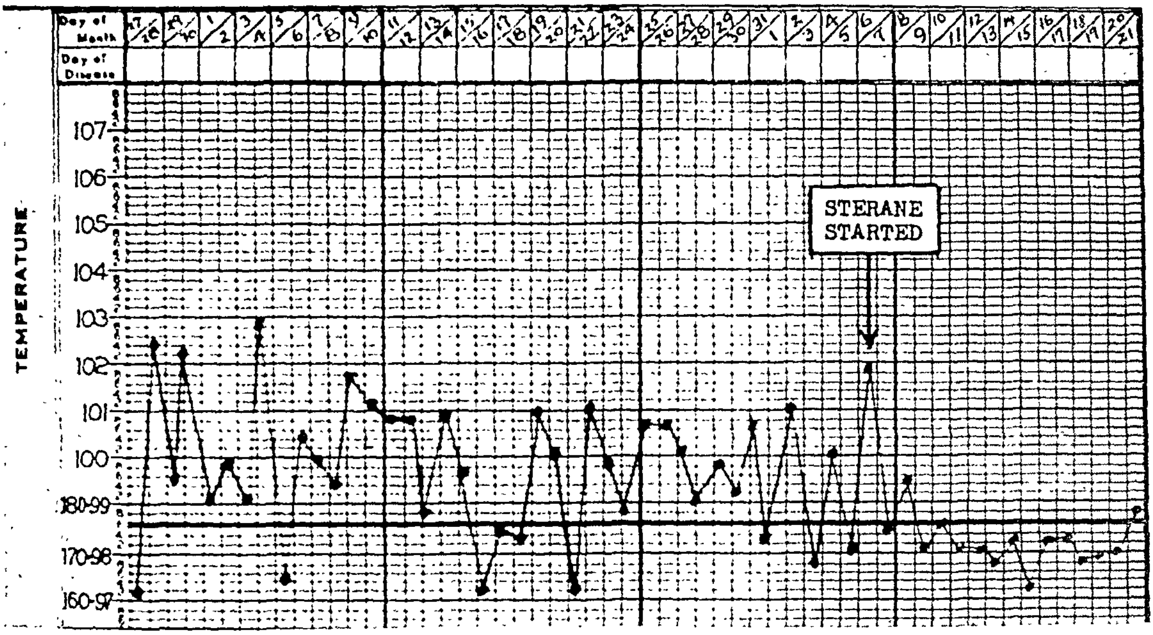

Fig. 3 (case 3).—Temperature chart of patient with far-advanced bilateral pulmonary tuberculosis before and during prednisolone therapy.

Terminal.—Twenty patients with terminal disease received steroids early in their treatment or later as a lifesaving measure. Some, who were in our original treatment group, were practically moribund when steroid therapy was started. Although there were five deaths, it was felt that the remaining 15 patients would also have died had it not been for use of prednisolone. Following is a typical case history.

CASE 3.—A 42-year-old man was admitted to one of our hospitals on Sept. 9, 1957, with far-advanced bilateral pulmonary tuberculosis and sputum positive for acid-fast bacilli. Toxicity was evident, with temperature of 105 F (40.5 C) daily, profuse perspiration, and delirium, and the case appeared to be terminal. He was placed on triple drug therapy. No improvement was seen clinically or by x-ray after one month, and toxicity was still present. There was little, if any, change after two months of triple drug treatment, so he was placed on prednisolone therapy on Nov. 7, 1957. Two days later, his temperature became normal for the first time since admission (fig. 3). By March 11, 1958, there was marked clinical and x-ray improvement (fig. 4), negative sputum cultures, and a weight gain of 20 lb. (9.1 kg.).

Allergic.—There were 21 patients who had allergic reactions to either streptomycin or isoniazid, all of whom still required chemotherapy. Desensitization with gradually increasing dosage, together with steroid therapy, was successful in all but one of these patients. She continued to show allergic reactions, could not tolerate any drugs, had a massive hemorrhage, and died. The other death occurred within 24 hours after operation. Prednisolone therapy had been discontinued five weeks prior to operation, and the patient had received no prednisolone before or after operation. This illustrates the definite need for steroid therapy in any patient who receives these drugs within one year prior to operation or in the presence of infection. In the remaining 19 patients, desensitization was accomplished and 7 had successful operations.

Active with No Response to Drugs.—Patients with resistant, chronic tuberculosis, who have apparently achieved their maximum improvement with present-day antituberculosis therapy, form a serious public health problem. The 66 patients in this group still had evidence of active disease with cavitation or positive sputum findings, although clinically many did not show toxicity. Several factors must be recognized in analyzing such cases: resistance of the tubercle bacillus to available drugs, poor host resistance, and possible chronic adrenal insufficiency. We believed that steroid therapy could not alter bacterial resistance but that some changes might occur. Every means to improve host resistance was used, such as adequate diet, supplemental vitamins, and adequate rest, with no further improvement. The possibility of chronic adrenal insufficiency, verified by low 24-hour urine levels of 17-ketosteroids, was considered a probable indication for steroid therapy. Although the *modus operandi* is not definitely known, we did see improvement in 36 of these patients, 4 of whom had successful operations. The remaining 24 showed no change, either clinically or by x-ray, and 6 died. The following case report is typical of this group of patients.

Case 4.—A 53-year-old man was hospitalized on Jan. 30, 1957, with a diagnosis of far-advanced active bilateral pulmonary tuberculosis. Because of toxicity and extensive disease, he was given triple drug therapy. On June 19, 1957, after almost six months' treatment, there was only slight improvement, with partially resistant organisms. At this time, prednisolone was added to the regimen. There was marked clinical improvement with extensive clearing seen on x-ray by Aug. 15, 1957 (fig. 5). One week later, artificial pneumoperitoneum was started, and on Oct. 3, 1957, his sputum cultures became and remained negative. During the first six months of treatment, he had gained 4½ lb. (2 kg.), but during the six months on prednisolone therapy he gained 25 lb. (11.3 kg.). At the time of writing he is being considered for operation.

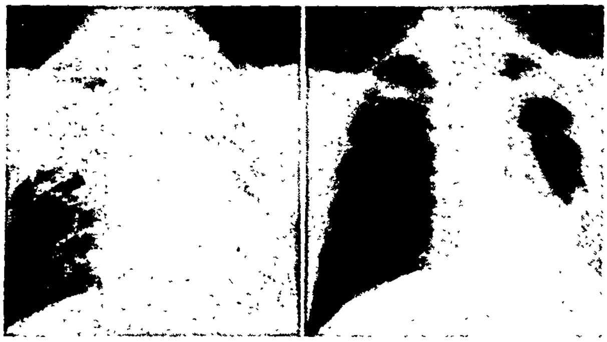

Fig. 4 (case 3).—Roentgenograms taken before prednisolone therapy was started (*left*, Nov. 4, 1957) and after four months of therapy (*right*, March 11, 1958), showing extensive clearing.

Sarcoidosis

Six patients with proved cases of sarcoidosis were included in this study. One also had pulmonary tuberculosis, and all had acute pulmonary involvement due to sarcoidosis. Because of a possible relationship to tuberculosis, all patients were put on the prednisolone regimen with antituberculous therapy. There was excellent resolution in all patients, with marked improvement in the dyspnea of two. In view of the indefinite etiology of sarcoidosis,[6] it is our belief that steroids should be used in the acute manifestations of this disease. At present, the use of para-aminobenzoic acid is being evaluated by Dr. Chris Zarafonetis at Temple University School of Medicine.[7] To date, his results have been interesting, showing that resolution occurs more slowly and that this preparation may be less toxic. Possibly a combination of the two drugs might be of value, and this will be investigated.

Reactivation of Tuberculosis

Just as therapy with antibiotics has been complicated by side-reactions, that with corticosteroids has also produced reactions which could diminish its usefulness. One must always remember that potent drugs, while effectively controlling and curing certain diseases, can also be dangerous by altering other physiological or chemical body functions. The successful results in the treatment of rheumatoid arthritis, bronchial asthma, nephrosis, lupus erythematosus, and other diseases are apparently due to the nonspecific, antirheumatic, anti-inflammatory, and antiallergic activity of the steroids. Although many of the electrolyte changes, fluid retention, gastric ulcers, and blood changes seen with use of the original cortisone drugs are not common with the prednisolone compounds, serious side-effects can still be seen.

As chest specialists, we have been seeing an increasing number of patients with reactivated pulmonary tuberculosis who have received steroids for a variety of diseases. During the past year, we have seen 58 patients in whom active tuberculosis developed during or after steroid therapy without antituberculosis drugs. These patients had been treated for the following diseases: rheumatoid arthritis (16), bronchial asthma (15), sarcoidosis (7), periarteritis nodosa (1), lupus erythematosus (8), allergic dermatitis (5), adrenal cortical hypofunction (1), ocular diseases such as uveitis (4), and polycythemia vera (1).

Only such a small number of such reactivations, compared to the large amounts of steroids being used, would not be serious. However, it is our belief that many, many more "breakdowns" occur which are not recognized or treated. The following case history is typical of this complication of steroid therapy.

Case 5.—A 57-year-old man was first hospitalized on Nov. 15, 1956, with migrating arthralgia, hepatomegaly, and rash, and a definite diagnosis of lupus erythematosus was given. He received hydrocortisone alternately with ACTH. There was a total of four hospital admissions for exacerbations of the lupus erythematosus, which always responded to steroid therapy. His last discharge was on Jan. 12, 1958, and he was readmitted on Feb. 28, 1958, with anorexia, productive cough, occasionally blood-tinged sputum, and weight loss. Reviewing his x-rays, we found that the one taken on Oct. 4, 1957, appeared to be within normal limits (fig. 6 *left*), but there were early changes in the left upper lobe on Jan. 5, 1958. However, this was not at the time considered significant. A roentgenogram taken Feb. 25, 1958, revealed extensive pulmonary tuberculosis with cavitation involving the left upper lobe, with spread (fig. 6 *right*). He was admitted to a tuberculosis sanatorium for further care.

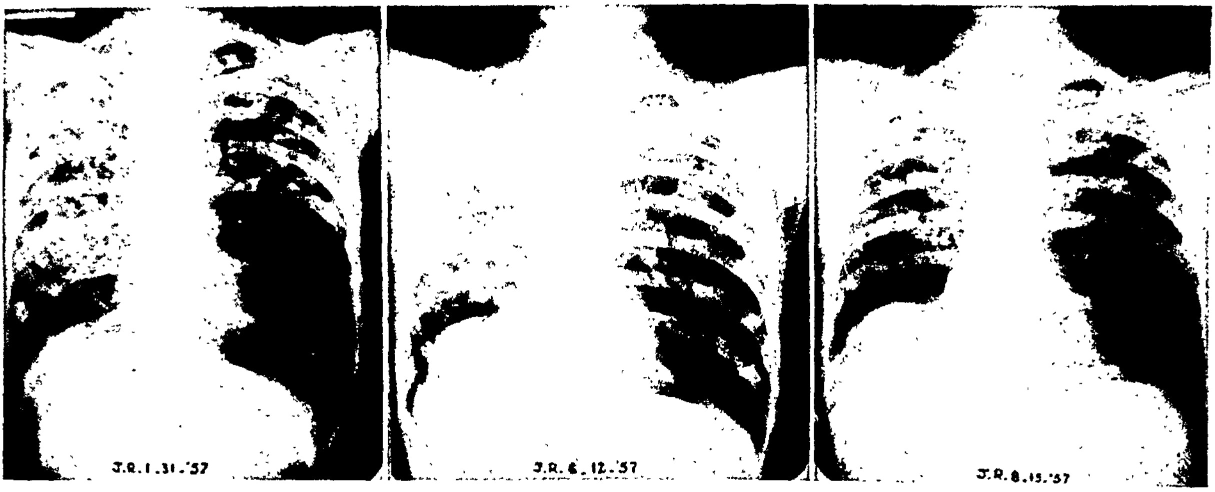

Fig. 5 (case 4).—Roentgenograms of patient with active tuberculosis no longer responding to present-day drugs, showing progressive improvement after institution of prednisolone therapy (*left*, Jan. 1, 1957; *center*, June 12, 1957; *right*, Aug. 15, 1957.

It is not the purpose of this presentation to discourage the use of steroid therapy. However, we urge all physicians using these drugs to investigate the presence of tuberculosis by skin test and x-ray and, if in doubt, to administer simultaneously the antituberculous drugs.

Other studies reveal that the anterior pituitary gland secretes about 1 unit of ACTH daily,[8] while the average daily output of hydrocortisone from the adrenal cortex varies between 12 and 20 mg. Most steroid therapy is given in doses far in excess of normal secretion. When such doses are given for periods exceeding 10 days, a relative suppression of adrenal function occurs. Many investigators, especially Lurie and co-workers,[2] have shown experimentally that excessive doses of cortisone have an adverse effect on tuberculosis. While the newer, more powerful analogs of cortisone, prednisone, and prednisolone are popular because they produce fewer side-effects, they are equally or even more dangerous when excessive dosages are used.

Comment and Conclusions

We are fortunate to be practicing medicine at this time, when so many effective drugs are at our disposal. The value of chemotherapy in the management of tuberculosis has been extensively shown. Steroids also have a place, when used in conjunction with chemotherapy, in the control of certain tuberculosis problems. They can be lifesaving in many acute forms of tuberculosis, are of great value in desensitizing patients allergic to drugs, and are helpful in many patients with chronic, resistant disease. They are also beneficial in treatment of patients with acute sarcoidosis (Boeck's sarcoid) with pulmonary involvement.

The use of steroids in other diseases, such as rheumatoid arthritis, bronchial asthma, and lupus erythematosus, has produced excellent results. There has, unfortunately, been an increasing number of these patients with reactivated pulmonary tuberculosis. Only when these drugs are used judiciously, that is, the minimum dosage for the shortest period necessary to obtain the desired effects, are complications diminished. Intensive skin testing and chest x-ray of every patient receiving steroids, with simultaneous chemotherapy when in doubt, will tend to safeguard against tuberculosis reactivation. These findings illustrate the paradox that a powerful drug can produce disastrous results when used where indicated and yet can produce beneficial results when used where contraindicated—but used wisely.

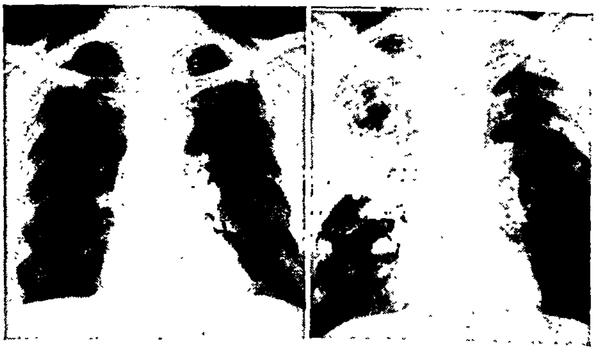

Fig. 6 (case 5).—Roentgenograms of patient with pulmonary tuberculosis reactivated by steroid therapy (*left*, Oct. 4, 1957, *right*, Feb. 25, 1958).

6601 N. 21st St. (38) (Dr. Shubin).

The prednisolone used in this study was supplied as Sterane through Dr. Kenneth Dumas of Chas. Pfizer & Company., Inc., Brooklyn, N. Y.

ACCURATE PREGNANCY TESTING IN TRANQUILIZED PATIENTS

Jane E. Hodgson, M.D., St. Paul

The reported occurrence of false-positive results of pregnancy tests in patients taking certain tranquilizers has been investigated. The test in question involved the intra-abdominal injection of a urine concentrate from the patient into male frogs, and the production of spermaturia constituted a positive result. The 50 psychiatric patients in the present study were all receiving promazine, prochlorperazine, or perphenazine daily in substantial doses. Samples of serum were obtained for use in place of urine concentrates. Hyaluronidase was injected with the serum to facilitate adsorption. Two frogs weighing from 25 to 50 Gm. were used for each of the 50 tests. There was no evidence that the test carried out in this way would give false-positive results in patients receiving tranquilizers of the phenothiazine group.

In 1957 Foxworthy and Lehman [1] reported 75% false-positive results in pregnancy tests performed on male frogs with urine from nonpregnant patients receiving promazine (Sparine) hydrochloride. The total number of tests in their series was not stated. The urine was concentrated by the kaolin adsorption method. The use of serum for pregnancy testing was not discussed in this study.

In the past five years I have performed 1,100 pregnancy tests with Rana pipiens frogs with use of serum exclusively. The accuracy and the many advantages of serum as compared to urine in this method of pregnancy testing have been described in previous articles.[2] In spite of the fact that the use of phenothiazine compounds by the general public has markedly increased, I have not observed any false-positive reactions that might have been attributed to these drugs. It seemed of interest, therefore, to perform according to my method a series of pregnancy tests with serum from patients receiving large doses of perphenazine (Trilafon), promazine, chlorpromazine (Thorazine) hydrochloride, and related compounds, in an attempt to verify the findings of Foxworthy and Lehman.

Method

Tests were performed with Rana pipiens frogs weighing from 25 to 50 Gm. Proper care and refrigeration of the test animals were considered of prime importance.[3] For each 10 Gm. of frog body weight 1 ml. of serum was injected. Prior to injection 1 ml. of hyaluronidase (Wydase, stabilized solution containing 150 U. S. P. units per milliliter) and 3 ml. of sodium chloride solution were added to the serum as a diluent in order to hasten adsorption and prevent anuria.[2a] Injections were intraperitoneal. Two animals were used in each test. As I have found no seasonal variation in the reactivity of these animals, provided they are healthy, the tests were performed throughout the 12 months of the year.

From the Charles T. Miller Hospital.

Serums were obtained from 50 hospitalized psychiatric patients, both male and female, who were taking varying dosages of phenothiazine compounds: 17 were receiving clinical doses of chlorpromazine, ranging from 150 to 400 mg. per day; 26 were receiving promazine, in doses from 75 to 500 mg. per day; 5 were receiving prochlorperazine (Compazine), 60 mg. per day; and 2 received perphenazine, 12 to 20 mg. per day.

Interpretation of "Positive" Tests.—The criterion that Foxworthy and Lehman[1] used for a positive test was a low-power field loaded with actively motile frog sperm. In my laboratory the presence of even one or two spermatozoa constituted a positive reaction, although such would be described as a very weak positive reaction. When a response is weak it will often be noted in but one test animal, presumably the one with the greater reactivity. In such instances, in clinical testing apart from the present series, the test will be repeated in three or four days with subsequent clarification of the clinical problem. The weakly positive responses are usually explained by a subsequent abortion or by an extremely early stage of pregnancy, both of which conditions are characterized by low titers of chorionic gonadotropin. In two tests performed apart from the present series a weakly positive response was obtained in two nonpregnant women at the time of ovulation, presumably as a result of the increased luteinizing hormone present at midcycle.

Results

In the 50 serum tests performed there were no strongly positive responses such as Foxworthy and Lehman described.[1] In the 100 test animals used there were two weak spermaturic responses and one moderately strong response. These three "false-positive" responses would have constituted no problem in clinical practice, inasmuch as in each instance the spermaturia occurred in but one of the two test animals, and the test would have been repeated. The association of these three responses with the patients' medication is indeed open to question.

Report of Cases.—A 42-year-old woman was receiving 150 mg. of promazine and 50 mg. of mephentermine (Wyamine) daily. A serum test performed on her third cycle day resulted in one negative response and one weakly positive reaction. In the latter, the frog became very limp but later recovered. In recent Russian experiments[4] spontaneous spermaturia was observed to occur in frogs operated on by Sechenov's method (sectioned anterior to the optic lobes with removal of the anterior brain). According to Davydova's opinion the spontaneous spermaturia occurring in 25 of 115 operated test animals is due to the release of the centers in the cord from the inhibitory influence of the higher nervous centers. This may explain why occasional spontaneous spermaturia occurs when the frogs are in poor condition or in a terminal state.

A 27-year-old woman was receiving 150 mg. of promazine and 37.5 mg. of mephentermine daily. A serum frog test performed at midcycle resulted in one negative and one fairly strong positive response appearing 90 minutes after the injection of serum. This weakly positive response may have been associated with ovulation.

A 27-year-old man in an extreme state of agitation was receiving 300 mg. of chlorpromazine daily. Result of one frog test was negative, and one showed a very weakly positive response (one to two sperm per high-power field) appearing two hours after injection. A third frog test performed with urine concentrate was negative. This patient was tested one week later when his agitation had subsided and the response was negative, although the dosage of chlorpromazine remained unchanged. This positive response could possibly be associated with the patient's state of agitation. The induction of spermaturia in the frog by injection of epinephrine has been pointed out.[4]

Comment

Since the completion of our series an article has appeared by Hilbert[5] in which he reports 43% false-positive reactions in a series of 30 nonpregnant patients receiving promazine and chlorpromazine. These tests were performed with urine specimens concentrated by the kaolin adsorption method. On three of these patients with false-positive results simultaneous serum tests were performed with correctly negative responses. The author speculated as to whether the failure of the serum to result in a false-positive reaction indicated that the substance giving the false-positive result was an excretory by-product found only in urine. Until such a time as the excretory by-products of the phenothiazine compounds are isolated, we can only theorize as to the reason for the spermaturia caused by the injection of urine concentrate.

Most experimental work shows that tranquilizing drugs tend to produce inhibitory effects in the region of the hypothalamus.[6] One can only speculate whether this may be the mechanism for the production of spermaturia after injection of urine concentrate from tranquilized patients. It may definitely be concluded, however, that in frog tests performed with serum from patients receiving large doses of promazine, chlorpromazine, and perphenazine, false-positive reactions constitute no more of a problem than in any series of pregnancy tests where the slightest degree of spermaturia is carefully noted.

Conclusions

Foxworthy and Lehman[1] and Hilbert[5] have reported high incidences (75% and 43%, respectively) of false-positive results of tests performed on patients taking promazine or chlorpromazine. These false-positive reactions were obtained in tests with use of urine rather than serum.

I performed a series of 50 frog tests on a similar group of tranquilized patients with use of serum instead of urine. There were no actual positive reactions in the entire series. In 3 of the 50 tests weak spermaturic responses were noted with but one of the two test animals. Subsequent repetition of the tests as well as the use of urine concentrate failed to elicit any further spermaturia, and it was felt that factors other than the tranquilizers were probably involved in the production of these three reactions. In clinical practice a weak response in one frog is not accepted as a positive test but is questioned and repeated. Reactions of this nature should be no excuse for incorrect clinical diagnosis or unnecessary surgery.

False-positive pregnancy tests in tranquilized patients apparently can be eliminated by the use of serum instead of urine, which is an example of another advantage of the use of serum over urine in pregnancy testing.

MANAGEMENT OF WOMEN WITH POSITIVE VAGINAL CYTOLOGICAL FINDINGS

James H. Ferguson, M.D.
and
J. Allan Offen, M.D., Miami, Fla.

The authors have acquired experience with many thousands of cytological examinations of the cervix by obtaining smears from all gynecologic and obstetric patients. They are convinced that every woman deserves a cytological examination on the first visit, regardless of age or whether or not she is pregnant. The evidence indicates that positive cytological findings in the pregnant patient are fully as significant as in the nonpregnant. Punch biopsy is done in all cases of cervical lesions. When a histological diagnosis of intraepithelial carcinoma is made or when there is an unexplained positive smear, a cold conization of the cervix is performed. With the expanding number of such examinations, there are large groups of women who have positive findings on cytological examination and in whom frank malignancy does not exist. Management of these patients looms as the newest challenge gynecology has to meet.

Cervical and vaginal cytological studies are rapidly becoming routine diagnostic procedures in the examination of women. As a result, the group of women with positive findings on cytological examination is increasing in size. The management of this increasingly large group of women presents a new and important problem in gynecology.

When the cause for positive findings is an obvious malignancy, the course of action is fairly well defined; therapy depends on the histological diagnosis and the clinical stage of the disease. However, when the patient with positive findings does not have an obvious invasive cancer, and the cause for the presence of the exfoliated cells in question is unknown, the problem becomes perplexing. Because of the tremendous increase in the number of women having vaginal cytological examinations this problem is one that must be faced frequently. This situation poses the following questions: 1. What further diagnostic studies are indicated at the time? 2. What constitutes adequate observation of this patient? 3. How can the physician convince the patient of the need for long-term, constant, and

---

From the Department of Obstetrics and Gynecology, University of Miami School of Medicine, and Jackson Memorial Hospital.

consistent follow-up examinations, so that she will assume the responsibility for regular cytological re-examinations, without at the same time instilling a devastating cancerophobia?

Under the designation of patients with positive cytological findings are included those in whom Papanicolaou stains of smears from the cervix and vagina reveal the presence of exfoliated cancer cells or cells that are suspiciously like cancer cells in some of their morphologic characteristics. In this group would be classes 3, 4, and 5 from Papanicolaou's classification.

Materials and Methods

Our experience with cytological examinations at the University of Miami School of Medicine–Jackson Memorial Hospital is already large and still growing. Cytological examination of women was started in 1952 and expanded gradually. With the beginning of a full-time department of obstetrics and gynecology on July 1, 1955, our activities in the field of cytology increased rapidly. In the Miami area we care for practically all indigent patients who have cancer. At present we examine about 9,000 gynecologic patients cytologically every year. On the staff service we see about 55 patients with new cases of invasive carcinoma and 75 with intraepithelial carcinoma of the cervix each year. Because of our accelerated cytology program we are seeing more early carcinoma and discovering more cases of intraepithelial carcinoma of the cervix. The number of cases detected on our service tripled in each of the first three years of the department's history. One index to the extent of our experience lies in the number of conizations done to establish an exact diagnosis in many patients with positive cytological findings. During 1956 we performed 132 conizations of the cervix; in 1957 the number increased to 173; and in 1958 the number was 213.

Our service to patients and our ability to use our patients with positive findings for investigation have been aided by the establishment of a positive cytology registry[1] supported by the National Cancer Institute. This registry is similar to a cancer registry, containing continuous records of all patients who have positive findings and maintaining follow-up contact with these patients. At present about 720 women with positive findings are registered. The length of follow-up study in some of these cases extends as long as six years. We plan to maintain clinical contact indefinitely with all women with positive findings and thus accumulate a record of the natural history of women who exfoliate abnormal cells. Among the cases under observation are a fairly large number of women with positive findings who as yet have not been demonstrated to have cancer.

Some of the unanswered questions are: What will be the ultimate fate of these women? Must these women be expected to develop cancer of the cervix at a later date? Do women who have positive findings have an increased susceptibility to cancer of the cervix or any other part of the body? We hope that answers will be forthcoming from this study.

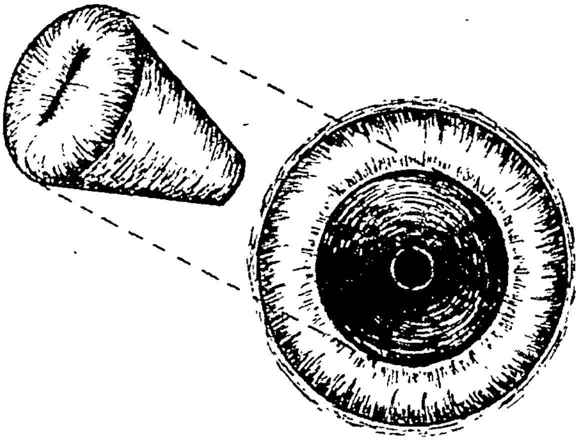
It is our firm conviction that cytological examination of all women is indicated at the first visit, regardless of the patient's age or whether she is pregnant. There appears to be a widespread belief that women below a certain age and women who are pregnant do not need cytological examination. Our experience does not support this contention; it is actually quite to the contrary. One-third of our patients with positive findings on cytological examination are under 30 years of age, and it is becoming clear that just as many women with positive findings during pregnancy have significant cervical disease that needs treatment as do nonpregnant women. Since often the only pelvic examination that many women have is performed when they are pregnant, it would be regrettable if this opportunity to do a cytological study were lost. Some investigators have concluded that cytological examination in pregnancy is not worth while because during this state there are too many misleading cytologists' reports. This also has not been borne out by our experience. We have found that positive findings during pregnancy are fully as significant as at any other time, and these women deserve as much attention as do those who are not pregnant. Since 1955 we have found 28 cases of intraepithelial carcinoma and 6 cases of invasive carcinoma complicating pregnancy. Most of these would have been undetected were it not for our cytology program.

Management of Women with Positive Findings

We interpret as a lesion any grossly visible change from a normal-appearing cervix, including eversion, erosion, cervicitis, or bleeding from any normal-appearing area. Such lesions are excised or sections are taken from them with a biopsy punch for microscopic study. This is done in all cases, regardless of the fact that a smear for cytological study is obtained at the same time. It is imperative to perform biopsies on all lesions, regardless of the availability of smears or the type of smear obtained. The most important reason for this conviction is that some malignant lesions may at times produce a negative result of the Papanicolaou smear.

In a patient who has a lesion a portion of it is excised not only for study but for biopsies. A piece of tissue is obtained from each of the four quadrants of the cervix. In some patients the Papanicolaou smear has given a positive result, but the result of biopsy has been negative for malignancy, the histological examination revealing only cervicitis. In such a situation a cone biopsy and a fractional curettage are done. As seen in the figure each cone biopsy specimen consists of a generous portion of tissue including all of the lesion on the ectocervix and the endocervix for a distance of at least 2 cm. Often the entire endocervical canal is included. To give the pathologist the best possible cone biopsy specimen a cold knife is used, and the hot cautery should not be employed. The cone specimen is obtained before dilatation of the cervix because dilatation can spoil the specimen for the pathologist. The ease with which we do cone biopsy has been greatly facilitated by injection of a dilute epinephrine and saline solution or saline and phenylephrine (Neo-synephrine) hydrochloride solution into the cervix. The hemostatic effect of this solution [2] allows us to obtain a good specimen. The injection of epinephrine does not distort the true histological picture on microscopic examination.

After the cone has been removed the remaining part of the endocervical canal, if any, is curetted. Then the internal os is dilated and the endometrial cavity is systematically curetted. The number of patients with positive findings in whom the results of punch biopsies are negative but cancer is found on cone biopsy encourages us to continue this practice. These cervices heal well without difficulty. Our experience indicates that in about seven weeks the mucosal defect has completely filled in and the cervix is well epithelialized and nulliparous in appearance. The endocervical canal takes somewhat longer for complete healing.



Cone biopsy specimen.

In the case of a patient who has a lesion of the cervix but in whom the cytological smear is negative, a biopsy specimen is obtained at the same time as the smear. If the result of biopsy is also reported to be negative for malignancy we then proceed directly with electrocauterization of the cervix. The cervix is treated with the hot cautery because we believe this to be the most effective therapy for cervicitis. It is also important to use this type of therapy when dealing with patients who are unlikely to return for subsequent clinic visits. Inability to return for prolonged outpatient therapy seems to be characteristic of many clinic patients. Therefore we can give them the best service and care by instituting the most definitive therapy at once. Such patients are asked to return in about five weeks to make sure the cautery has destroyed the lesion and that the tissue has been replaced by normal tissue. If healing is incomplete, the lesion is then cauterized again.

One-seventh of all of our patients with positive findings on cytological examination have no lesion grossly visible on the cervix. When a positive cytological report is received on such a patient, our practice has been to bring the patient back to the clinic as soon as possible and perform quadrant punch biopsies. An endocervical biopsy and endometrial biopsy are sometimes done at that time. If these are negative for malignancy, and cervicitis is the only disease reported, the patient is simply observed. She is seen frequently, at least once a month, and each time a smear is taken. If the repeat smears are negative then we continue to do smears monthly for six months and then every three months for the next six months. If all smears remain negative the patient is returned to the annual cytological examination schedule, which we feel should be a routine procedure for every woman. However, if this patient with a negative result of quadrant biopsy is again noted to have a positive smear on subsequent examination, then a cone biopsy and fractional curettage are done. We are becoming increasingly aware that carcinoma of the cervix may begin in the endocervical canal, beyond the reach of the punch forceps, rather than at the mucocutaneous border.

Appreciation of the origin of the neoplasm in the endocervical canal in many cases and the inconclusiveness of many punch biopsy studies is now changing the above procedure. We are frequently performing a cone biopsy at once when a woman has positive findings and a perfectly normal cervix.

Pregnancy

The pregnant woman with positive findings on cytological examination is approached in much the same way as the nonpregnant patient. For one thing, we frequently deal with women who have never had a pelvic examination and cytological study or at least have not had them for a long time. In such women this may be the only opportunity to detect an important cervical lesion and to cure it. Second, as our experience with the cytological study of pregnant women increases, there is found to be very little difference between pregnant and nonpregnant women, and so it is wisest not to assume that cytological change is due to pregnancy. We have been finding approximately the same incidence of basal cell hyperplasia, intraepithelial carcinoma, and invasive carcinoma among our pregnant patients as in the comparable age groups among the nonpregnant.

In the case of a woman in early pregnancy whose Papanicolaou smear gives a positive result, even if there is no lesion, we do a quadrant biopsy and if it is negative we continue to observe the patient. This means frequent visits and frequent cytological studies. If the quadrant biopsy shows basal cell hyperplasia or intraepithelial carcinoma, or if the positive cytological findings persist, a cone biopsy is performed. Cone biopsies are performed during pregnancy in exactly the same way as in the nonpregnant state. Here again, the injection of a hemostatic solution into the cervix makes the operation simpler. In a patient in advanced pregnancy who is expected to deliver reasonably soon the procedure differs slightly. It is occasionally wise to wait until after pregnancy has terminated before carrying out a vigorous investigation; for one thing, the delay until a definite study is done will not be long, and it may be technically more difficult to excise portions of the cervix in late pregnancy. Our attitude in this regard may change as our experience grows.

We have done 34 cone biopsies in pregnant patients. There is some risk associated with it, but our experience is not large enough to determine the exact extent of the danger. At least two patients have had an abortion soon after conization. The incidence of premature delivery may be significant. It seems that excision of a cone during pregnancy must be considered a calculated risk.

In pregnant patients a quadrant biopsy is done. The bleeding here usually can be controlled by firm pressure with a sponge but sometimes a tampon is inserted for several hours to control the bleeding. One patient had bleeding from a punch biopsy which necessitated her admission to the hospital. If results of the quadrant biopsies are negative the patient is allowed to go on to the point of delivery. In some women at the time of delivery additional biopsy specimens have been taken while the patient is under anesthesia. At delivery the patient is carefully observed by inspection of the cervix and cytological studies. If the smears continue to be positive, a cone biopsy and a fractional curettage are done 12 weeks post partum. This period of 12 weeks is arbitrarily selected and may not have any particular advantages. Many women who have positive findings on cytological examination during pregnancy continue to have them until 12 weeks post partum. If a patient who had positive findings during pregnancy should consistently have negative findings post partum, there may be some rationale for continued cytological observation without more vigorous study.

Women who have positive findings without associated lesions or demonstrable cause or who have intraepithelial carcinoma are allowed to deliver vaginally unless there are obstetric contraindications. Patients who just before term are discovered to have invasive carcinoma are delivered by cesarean section.

Summary

Vaginal and cervical cytological studies are rapidly becoming routine gynecologic diagnostic procedures. With the expanding number of such examinations there are also large groups of women who have positive findings on cytological examination and in whom frank malignancy does not exist. Appreciation of the size of this group and of the ramifications of the problem they present is bound to increase. Management of these patients looms as the newest challenge gynecology has to meet.

This study was supported in part by a grant from the National Cancer Institute, National Institutes of Health.

MALIGNANT DISEASE AND THE MENOPAUSE.—During this time [the menopause] the individual must make mental and physical adjustments. . . . If she has been sensibly forewarned, so much the better, but unfortunately the mythology concerning the climacteric is still passed on from woman to woman and has survived for so long that many women are reluctant to consult their family doctor about symptoms that are sinister. The practitioner, however, may not be free from blame, for this physiological process too easily becomes a diagnostic wastebin into which various complaints may be discarded. This may mean that symptoms of ominous prognostic significance may be cast aside lightheartedly as all forming part of the "change," the real cause of the symptoms being overlooked. . . . These wrong ideas . . . may lead to diagnostic delays and errors which may cost the patient her health—if not her life. The most obvious example is the supposition that irregular or heavy bleeding about the time of the menopause is to be regarded as a matter of course and only another annoying manifestation of the climacteric.—J. S. Tomkinson, M.B., F.R.C.S., M.R.C.O.G., Malignant Disease and the Menopause, *The Practitioner,* May, 1959.

UTERINE CYTOLOGY—THE "FALSE-POSITIVE" REPORT

Elmer R. Jennings, M.D., Esther Dale, M.D., Harry M. Nelson, M.D., Osborne A. Brines, M.D.
and
Gerald Wilson, M.D., Detroit

Examination of vaginal and cervical smears gives results that generally agree with the result of subsequent study of tissues for biopsy, but occasionally the smear is reported as positive and the biopsy as negative. In a series of 12,885 women there were 100 whose initial cervical smear was reported as positive for malignant cells. In 58 of these the biopsy was positive; in 42 the diagnosis of malignancy was not confirmed by biopsy during the immediate follow-up period. In 37 of the 42 the cause of the discrepancy was found to be an error of sampling or of interpretation. In the remaining five cases no explanation was found.

More than 15 years have passed since the report of Papanicolaou and Traut[1] on the diagnosis of uterine cancer by the vaginal smear was published. In that time there has been abundant confirmation of the fact that it is possible to diagnose carcinoma of the cervix and endometrium by examination of vaginal and cervical smears. Results of treatment for cancer of the cervix, unlike those for carcinomas which develop in many of the internal organs, are easily correlated with the stage of the disease at the time therapy is instituted. Effective means are available for the treatment of early carcinoma of the cervix, and early and adequate treatment for this malignancy should result in the cure of at least 90% of the women afflicted.

Although in general there is excellent correlation between cytological and tissue investigations, a false-positive report of the smear will occasionally appear; that is, the smear will be reported as "positive" and the biopsy specimen as "negative." This is distressing for both the physician and the patient and can cause much anxiety, apprehension, and expense. The study herein reported was begun in an effort to find the ultimate disposition of cases in which there is a failure of correlation of the tissue with the cytopathological diagnosis.

Material and Methods

From Jan. 1, 1956, through Feb. 17, 1958, 12,885 female patients were examined at the Yates Memorial Clinic. Of this group there were 100 patients whose initial cervical smear was reported as positive for malignant cells. Of these patients at the Yates Clinic a positive biopsy report was obtained in 58 within 10 days of the initial examination. For the remaining 42 patients the positive smear was not confirmed on immediate follow-up examination. Efforts were made to reach these patients through their private physicians and to obtain additional tissue which might reveal the presence of malignancy. These attempts were successful in 98 of the 100 patients, there being 2 in whom no biopsy was performed. In addition, all "negative" biopsy reports were reviewed by a panel of three pathologists. The smears from those patients whose diagnosis of carcinoma was not confirmed were reevaluated. It was thought that by these methods it should be possible to define the reasons for the failure of correlation between the cytological report and the initial tissue examination.

Results.—The initial biopsy confirmed the diagnosis of malignancy by cytological examination in only 58 of the 100 cases. The 42 apparent discrepancies were resolved in the following manner: Two patients had cervical biopsy studies done at a clinic other than the Yates Clinic which confirmed the presence of malignancy. For 15 patients the diagnosis of carcinoma of the cervix was established by examination of additional tissue—7 by conization, 7 by hysterectomy, and one by punch biopsy. Of this group five were proved to have invasive carcinoma of the cervix. For four patients the diagnosis of malignancy was not confirmed until it was realized that the carcinoma was not of the cervix but of another site, in three of the endometrium and in one of the vulva. A review of six of the original biopsy studies by a panel of pathologists resulted in a change of diagnosis from "benign, atypical hyperplasia" to "malignant, noninvasive carcinoma." Thus it happened that the positive smear diagnosis was confirmed in an additional 27 cases. Review of the smears resulted in downgrading from "positive" to "atypical" or "suspicious" in eight cases. There were five cases in which the biopsy specimen appeared adequate and benign, and yet the smear was still regarded as positive. The remaining two patients had no biopsy examination.

Comment

There are several reasons for failure to confirm a diagnosis of cancer made by cytological examination of cervical and vaginal cells. Among these are

---

From the Yates Memorial Clinic and Wayne State University.

(1) mistaken identity of patient or specimen; (2) improper identification of atypical, degenerated, or otherwise altered benign cells as malignant; (3) failure to perform biopsy; (4) failure to obtain an adequate biopsy specimen; for example, too small a sample, crushed tissue, material from uninvolved area, or carcinoma in tissue not sampled, such as endometrium; (5) improper evaluation of tissue changes in the biopsy specimen; or (6) unresolved problems.

Each reason for lack of correlation was seen in the present series except improper identification. By far the largest group of errors is that listed as failure to obtain adequate material for biopsy. Of the original 42 discrepancies 21 were in this category. The biopsy specimen must be adequate with regard to size, must come from an involved area, and must be handled in such a way as to allow an adequate pathological examination. Tissue which has been crushed or in other ways damaged, so that fine histological detail is no longer discernible, must be considered inadequate. Any burning of the tissue by various types of electrical instruments will render it unsuitable for histological examination. Sometimes the biopsy specimens are too small or are taken from the portio vaginalis when the involved area is near the internal os. A common mistake was made by gynecologists who dilated the cervix and curetted the endometrium before doing the cervical biopsy. Under such circumstances it often happened that the biopsy specimen was inadequate because all of the surface epithelium had been removed from its normal position.

Lest it be thought that all cases which were diagnosed by additional material from the cervix were noninvasive carcinoma, it should be emphasized that of the seven instances in which cold conization of the cervix revealed the malignancy when the punch biopsy specimen had appeared to be nonmalignant four proved to be invasive carcinomas. This is an important consideration, for it is not generally appreciated that one can miss an invasive carcinoma of the cervix by punch biopsy. Of the seven instances in which a hysterectomy changed the diagnosis one was found to be an invasive carcinoma of the cervix. In four cases the biopsy specimen was inadequate because it was of the wrong organ or tissue. Three of these were found to be carcinomas of the endometrium, and the original biopsy specimens were from the cervix. The fourth case was a carcinoma of the vulva. These data emphasize the important part that the clinician plays in ferreting out the cause of the discrepancy between the positive cytological report and the original biopsy diagnosis.

The next largest group of cases in which the discrepancy was resolved was that in which the original cytological diagnosis of a positive smear was incorrect. This happened in 8 of the 100 cases and was revealed when, on review of these smears, it was realized that cell alterations caused by degeneration, improper fixation, and infection had been mistakenly diagnosed as malignant change. The number of these cases should be few and ordinarily will reflect the experience of the cytologist. With better understanding of the cell changes resulting from various benign reactions there should be a reduction in the number of true false-positive smear diagnoses made.

Another facet of this problem which is deserving of emphasis is the matter of evaluation of tissue changes as present in the biopsy specimen. It is regrettable but nonetheless true that the diagnosis of carcinoma in situ is still a subjective matter, to some extent. The definition of noninvasive carcinoma which has been utilized in this study stipulates that the change in the epithelium must be such as to resemble that seen in invasive carcinoma. Since there are several varieties of patterns of invasive carcinoma, it follows that there will be corresponding patterns for intraepithelial carcinoma. Despite wide experience in this area there will be truly borderline cases in which the changes appear to be more than atypical hyperplasia and still somewhat less than noninvasive carcinoma. For this study we have attempted to resolve these problems by having a panel of three pathologists review the sections. The examination of the sections was made independently by the reviewing board and the diagnoses were changed from "benign" to "malignant" only when at least two of the pathologists thought, on review, that the correct diagnosis should be intraepithelial carcinoma. There are pathologists who are unwilling to make the diagnosis of noninvasive carcinoma. All smear diagnoses which are called "positive" because of the presence of exfoliated cells from noninvasive carcinoma will be considered by these pathologists as "false-positives." There is no doubt that we should have a more concise and easily applied definition of intraepithelial carcinoma.

Even after prolonged follow-up study, review of original and additional biopsy material, and reexamination of the cytological smears, there were 5 cases of the 100 which remained unresolved. In these the smear diagnoses were still "positive," but there had not been any histological confirmation. These could properly be considered as cases of unconfirmed positive cytological diagnoses. There was a good deal of anxiety and expense for these patients and their physicians; and, at least to date of writing, there has been no benefit to the patient. Possibly a longer period of follow-up will reveal a malignancy which has not been detected. On the other hand, it may be that these cases are examples of changes within the cells (in the smears) which rarely occur in the absence of malignancy and are indistinguishable from the changes that reflect the development of cancer.

Summary

Results of the first biopsy study at the Yates Clinic of 100 patients with positive cervical or vaginal cytological findings confirmed only 58 of them. All but 5 of the 42 apparent discrepancies were subsequently resolved by study of additional biopsy material, review of the original biopsy studies, or review of the original smears.

TROPHOBLASTIC PULMONARY THROMBOSIS WITH COR PULMONALE

REPORT OF A CASE DUE TO MALIGNANT HYDATIFORM MOLE OF FIVE YEARS' DURATION

Robert J. Fahrner, M.D., Andrew J. McQueeney, M.D., Jack M. Mosely, M.D.
and
Robert W. Petersen, M.D., Santa Barbara, Calif.

The patient's first pregnancy, in 1953, terminated at five and one-half months with the expulsion of a mass that was described, on the basis of microscopic examination, as a benign hydatiform mole. Five years later, after repeated pulmonary complaints, the patient was found to have infiltration of the left lung field and left pleural effusion. After hospitalization, her condition deteriorated steadily. Postmortem examination confirmed the clinical impression of multiple pulmonary infarction and cor pulmonale. The infarcts were due to choriocarcinomatous tumor thrombi originating from a Y-shaped saddle type of trophoblastic tumor obstructing the pulmonary arteries bilaterally. It is unlikely that administration of chorionic gonadotropin to the patient in the five-year interval for infertility stimulated trophoblastic proliferation, but this possibility cannot be entirely excluded.

Blood vessel invasion by the trophoblastic covering of the ovum occurs normally at the implantation site, and trophoblastic deportation to the lungs is estimated to occur in 80% of normal pregnancies; spontaneous regression is the rule. In the present case, however, angioinvasive trophoblast filled the entire pulmonary arterial tree after malignant transformation of a hydatiform mole of five years' duration. Death was ultimately due to multiple progressive pulmonary infarction and cor pulmonale.

Report of a Case

On March 31, 1958, a 30-year-old woman was admitted to the St. Francis Hospital, Santa Barbara, Calif., with a chief complaint of shortness of breath for one week. History revealed an infertility problem dating back to her first pregnancy, which terminated at five and one-half months, on Oct. 1, 1953, with the passage of a 450-Gm., bloody mass containing numerous grape-like structures having the appearance of typical hydatid-like cysts. The pathological diagnosis of benign hydatiform mole was made on the basis of microscopic examination at that time, but recent reexamination has shown foci of atypical trophoblastic growth on the surface of blood clot (fig. 1).

Dilation and curettage performed on Oct. 5, 1953, was reported as showing "necrotic decidual tissue." A Friedman test was reported to give negative results on Oct. 23, 1953, but doubtful results on Dec. 17, 1953. Chest x-ray on March 30, 1954, was reported to show negative findings.

During the next three years, five subsequent pregnancies, each terminating in a spontaneous abortion before the sixth week, were followed by curettage, and at no time was any molar tissue subsequently identified.

She was referred to one of us (R. J. F.) as having an infertility problem in September, 1956. Clinical and laboratory evaluation was concluded in Decem-

ber and seemed to indicate a deficiency in progesterone and chorionic gonadotropin. Consequently, a three-month course of hormone therapy was instituted Jan. 17, 1957. Menses remained normal, and with each cycle she received 300 mg. of progesterone orally plus 6,000 I. U. of chorionic gonadotropin (Antuitrin-S). The final course of chorionic gonadotropin therapy was completed on April 8, 1957.

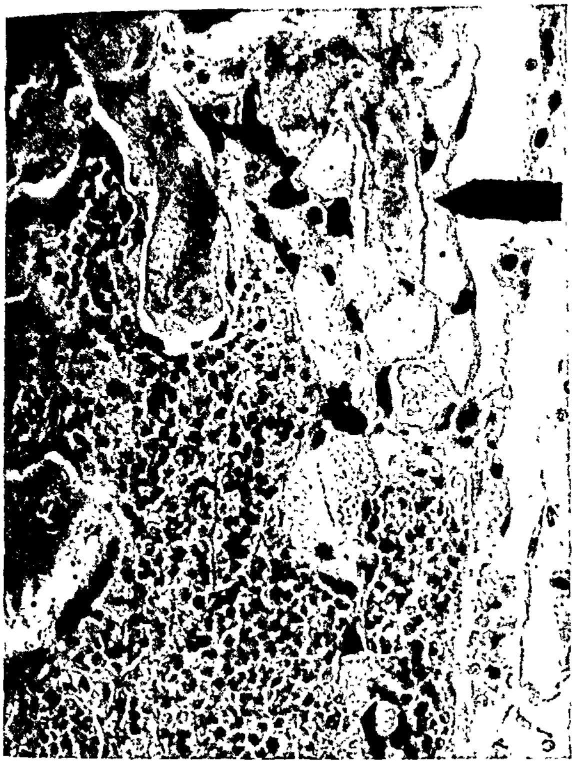

Fig. 1.—Photomicrograph of mole, taken in October, 1953, showing atypical trophoblastic growth on surface of blood clot. Note absence of normal villose stroma (hematoxylin and eosin stain, × 430).

In May, 1957, the patient had an episode of "pneumonia" of two weeks' duration. This consisted of pleuritic chest pain on the right side and fever, together with apprehension and shortness of breath but no hemoptysis. Roentgenogram of the chest revealed an infiltration at the right base.

On June 12, 1957, the patient suspected she was pregnant, and a frog test was reported to give positive results. Chorionic gonadotropin was again administered from the 14th to the 19th of June. Profuse bleeding followed, necessitating dilation and curettage June 25, which revealed, on microscopic examination, "endometrium, proliferative phase; nothing suggesting a recent pregnancy."

In early November, 1957, the patient again had a four-day episode of pleuritic pain over the right side of the chest, associated with cough. On Nov. 20, an endometrial biopsy was obtained and showed benign endometrium in the proliferative phase with focal glandular atypism. Diagnostic dilation and curettage was performed on Dec. 10, 1957, but microscopic examination revealed only "atrophic benign endometrium, proliferative phase, without evidence of atypism." A frog test on Dec. 9 was again reported to give positive results. Chest x-ray on Dec. 10 revealed a normal chest.

In January, 1958, she developed pain over the left side of the chest, breathlessness, and cough, associated with occasional hemoptysis; she was hospitalized at that time because of infiltration in the left lung field and left pleural effusion. Within one week, infiltration became nodular in appearance and more extensive. It was the opinion of the roentgenologist at this time that metastatic disease to the lungs or pleura should be given serious consideration (fig. 2). Because of the pleural effusion associated with this infiltration, tuberculin and coccidioidin tests were performed and gave negative results. Sputum was negative for acid-fast bacilli.

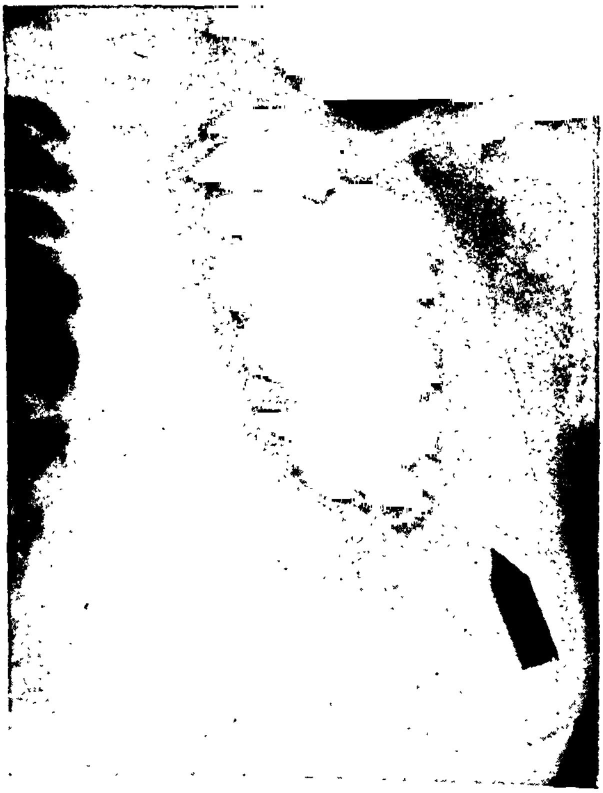

Fig. 2.—Roentgenogram, showing pleural effusion on left with multinodular infiltration.

Chest fluid gave positive findings on a pregnancy test in a 1:5 dilution. The urine pregnancy test likewise gave positive results but only after concentration, indicating a chorionic gonadotropin titer in the chest fluid approximately 250 times higher than that of the urine. At this time, four and one-half years after the molar pregnancy, the quantitative chorionic gonadotropin titer on the urine was only 4,800 I. U. per 24 hours, i. e., less than one-tenth the maximum titer obtained in a normal pregnancy.

In February, 1958, exploratory thoracotomy revealed approximately 20 small, recent, hemorrhagic nodules in the left lung, the majority in the left lower lobe; one of these was excised for pathological examination, which showed a hemorrhagic infarct with no demonstrable metastatic disease. A diagnosis of chorioadenoma was considered, and total hysterectomy and bilateral salpingo-oophorectomy was performed March 12, 1958. The ovaries were not enlarged or cystic, showing, microscopically, a heterotopic decidual reaction but no evidence of excessive lutein response. Pathological examination and careful reexamination failed to show evidence of trophoblastic foci in the uterus or uterine adnexa.

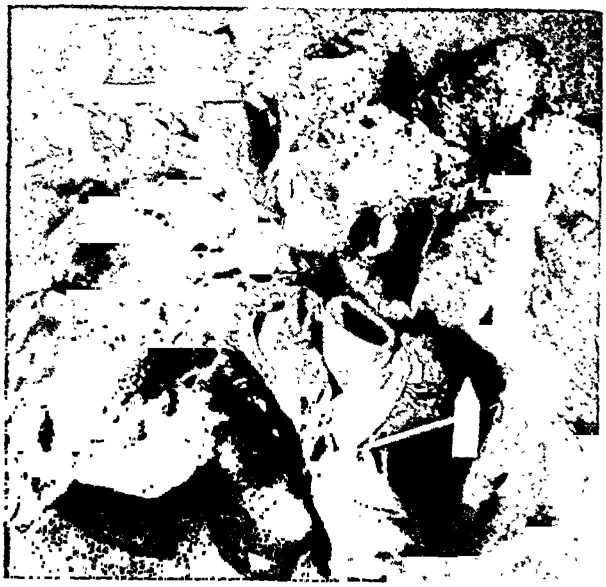

Fig. 3.—Heart-lung preparation with pulmonary conus opened, showing saddle thrombus at bifurcation of pulmonary artery. Note multiple pulmonary infarcts and cor pulmonale.

The patient was readmitted to the hospital on March 31, 1958, primarily because of increasingly severe shortness of breath for the past week, with associated palpitation and a sharp, pleuritic type of chest pain localized just beneath the left breast. She had been coughing up moderate amounts of blood-streaked sputum and had had an intermittent low-grade fever with fairly severe night sweats for the past three weeks. On the day of admission she was dyspneic at rest, and a chest roentgenogram at this time showed tiny multiple nodules and a marked increase in the vascularity of both lung fields, with enlargement of the pulmonary artery segment in the region of the right hilum. Findings were thought to be due to multiple embolic phenomena with associated pulmonary arterial hypertension.

The patient improved slightly on anticoagulant and oxygen therapy, but on April 10, 1958, she complained of increasing dyspnea, became cyanotic, and suddenly died. The clinical diagnosis was multiple pulmonary infarctions, pulmonary hypertension, pulmonary embolism, and cor pulmonale. In spite of the long history, normal pelvic organs, and low chorionic gonadotropin titer, it was felt that these changes were in some way related to the molar pregnancy of October, 1953, four and one-half years prior to death.

Postmortem examination confirmed the clinical impression of multiple pulmonary infarction and cor pulmonale. Pulmonary infarcts originated through propagation of a large, Y-shaped, saddle type of trophoblastic tumor thrombus which was found obstructing the pulmonary arteries bilaterally (fig. 3). The older portion of the saddle thrombus was densely adherent to the posterior wall of the pulmonary artery for a distance of 2.0 cm.; the surface of the thrombotic mass appeared filamentous or

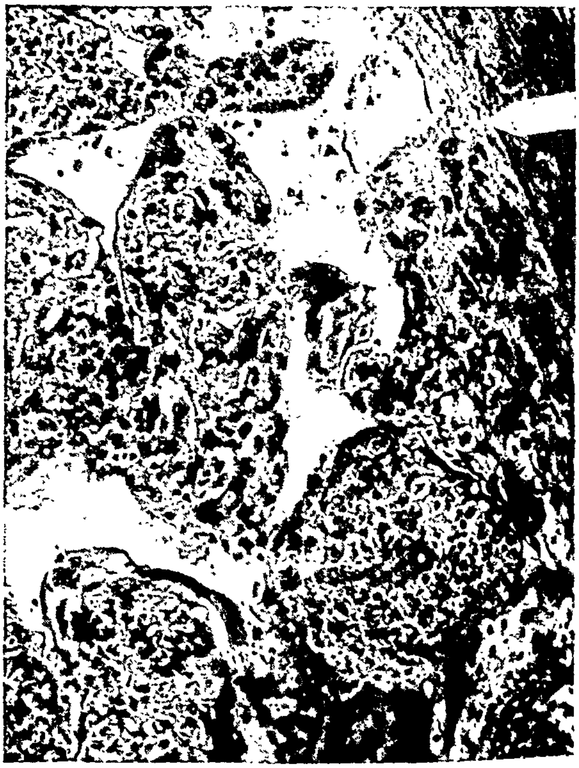

Fig. 4.—Photomicrograph, showing intravascular choriocarcinomatous thrombus within pulmonary infarct. Note absence of villose stroma and fixation to arterial wall, upper right (hematoxylin and eosin stain, × 430).

finely papillary, and the entire thrombus had a spongy, friable consistency, resembling placental tissue. The more recent propagating portions of the thrombus extended into the distal segmental portions of the pulmonary arterial system bilaterally but most marked on the left side. On microscopic examination, the tumor thrombus in the pulmonary artery was largely necrotic, but a thin surface film was formed by trophoblastic elements in an atypical villose pattern; identical thrombi were demonstrated within the more recent pulmonary infarcts (fig. 4).

The heart showed the dilated, hypertrophic right ventricle characteristic of well-established cor pulmonale; there was no evidence of endocarditis or mural thrombosis within the heart proper. The lungs showed multiple pulmonary infarcts, bilaterally, healed, organizing, and recent, with associated acute fibrinous pleuritis in the right upper and lower lobes. Individual infarcts ranged in size from 4 to 6 cm.; there was no evidence of extravascular pulmonary metastasis.

Microscopic examination showed the pulmonary infarcts to be due to multiple tumor thrombosis within segmental branches of the pulmonary arterial system. The arterial lumen in the center of recent infarcts was occluded by choriocarcinomatous tumor thrombi arranged in an atypical villose pattern; individual tumor masses were formed by cytotrophoblast covered by syncytial trophoblast, both appearing hyperplastic and atypical. The normal villose stroma was characteristically absent, but cellular pleomorphism was minimal and mitoses were rare (fig. 4).

No extrapulmonary choriocarcinomatous metastases were demonstrated. Of incidental interest, in view of the obstetric history, was the presence of a small chromophobic adenoma in the anterior lobe of the pituitary gland.

Comment

The occurrence of cor pulmonale due to multiple pulmonary infarcts is well recognized,[1] and two cases similar to the present one have been previously reported.[2] A unique feature of the present case, however, appears to be the bilateral involvement of both pulmonary arteries and their major branches by intravascular tumor thrombosis. The degree of cor pulmonale and the early history of pulmonary infarction confirmed by x-ray examination suggest that unrecognized tumor thrombus was established and propagating within the pulmonary arterial system for at least a year prior to death and probably long after disappearance of the primary uterine tumor. In the clear light of hindsight, a propagating saddle thrombus in the pulmonary artery might have been suspected because of the asymmetrical distribution of the pulmonary infarcts. For example, in one episode all infarcts appeared in the right lung, while in a later episode all infarcts appeared on the left. In contrast, multiple emboli from a peripheral source would more likely be distributed by chance to both lungs equally.

With respect to the malignant transformation of the hydatiform mole, it appears that its malignant potentialities were well established during the molar pregnancy five years before. Hertig,[3] after reviewing this material, called attention to the atypical trophoblastic growth in the original mole, emphasizing again the importance of examining microscopically all associated blood clots as well as molar tissue. This makes it unlikely that the administration of chorionic gonadotropin stimulated or influenced subsequent trophoblastic proliferation, although this possibility cannot be entirely excluded.

With the microscopic findings, the present case provides a kind of "missing link" in the transition from invasive mole to choriocarcinoma. The prominent villose growth pattern (fig. 4) is characteristic of mole, while the absence of stroma within individual villi is an important differential point in favor of choriocarcinoma.[4] It is noteworthy, however, that the tumor remains entirely intravascular, and this absence of invasion beyond vascular channels appears to be a characteristic feature.

Therapeutic management of this young primipara was conservative in line with the original benign tissue diagnosis, but, in retrospect, one must recall the comment of Novak and Seah[5]: "To insure removal of the occasional genuine choriocarcinoma, it is necessary to sacrifice a good many uteri harboring lesions which are not malignant and would usually regress and disappear."

CONTROL OF TETANUS SPASMS BY ADMINISTRATION OF MEPROBAMATE

Meyer A. Perlstein, M.D., Chicago

The course of tetanus has been studied in 39 patients treated with meprobamate. Among the 20 who were addicts to heroin (diacetylmorphine) there were 14 deaths; of the 19 nonaddicts only 4 died. Morbidity has been greatly reduced. Before the introduction of the meprobamate treatment, in a group of 51 patients there had been 33 deaths, 26 being among the 36 heroin addicts in the group. While the mortality among the heroin addicts remained the same, mortality among the nonaddicts was strikingly reduced by the use of meprobamate. In most patients, complete control of somatically induced seizures was attained by giving 400 mg. of meprobamate in 5 cc. of polyethylene glycol intramuscularly every four hours. Two case histories illustrate its effects, which are manifest within 15 minutes and last three or four hours after each injection.

In spite of the widespread use of tetanus toxoid in pediatric immunizations and in Army inductees, tetanus is still prevalent in certain areas of the United States.[1] At the Cook County Hospital in Chicago there have been approximately 20 to 25 cases a year. In India, Africa, the West Indies and South America,[2] and other areas of poor medical hygiene, the disease is extremely common. As a result of the use of antibiotics, tracheotomy, intravenous feedings, and improved nursing, in the last 20 years there has been a gradual drop in mortality from tetanus in the United States from about 75% to about 25%.[3]

At the Cook County Hospital there has recently been a change in the type of tetanus patients seen. Most of the patients in the past 10 years have been persons addicted to heroin (diacetylmorphine) in whom the disease resulted from use of contaminated heroin. There is usually a rapid onset of symptoms—24 hours or less, and a high mortality—over 90%. The prognosis in tetanus is more closely related to the rapidity of development of symptoms than to any other factor. In general, if the elapsed interval between the first symptom, such as stiff neck or trismus, and the first spasm is less than 24 hours, mortality is about 90%; if this period is between 24 and 48 hours, mortality is about 50%; if the period is between 48 and 96 hours, mortality is about 25%; if it is five days or over, mortality is about 10%. These clinical correlations are the subject of another paper.[4]

Nature of Spasm and Clinical Course

Sherrington[5] pointed out that the seizures of tetanus are physiologically identical with those of strychnine poisoning. In both conditions there is a loss of a reciprocal relaxation and in its place reciprocal facilitation occurs. Thus, any voluntary attempt at motion results in irradiated hyperactivity to the antagonist so that spasms occur primarily in the direction of action of the stronger muscle groups. An attempt to open the jaw results in a facilitation of the more powerful muscles that close the jaw so that the clinical picture of "lockjaw" appears.

These seizures are extremely painful, since the patient is conscious. Because they involve all of the muscles of the body, extensor spasms predominate. The spasms also involve the respiratory muscles and thus predispose to hypoxic episodes and pulmonary infections. In untreated patients these spasms may be sufficiently severe to cause compression fractures of the spine or even rupture of some of the muscles, e. g., rectus abdominis. Because of the increased irritability of the central nervous system, spasms may be precipitated by exteroceptive (somatic) stimuli such as bright lights, noises, pinpricks, or skin pressure. They may be triggered also by proprioceptive stimuli from passive movement of an arm or a leg, as occurs in turning the patient. Interoceptive (visceral) stimuli from gas in the gastrointestinal tract, an overdistended bladder, or mucous plugs in the bronchi may likewise precipitate seizures.

The early and obvious causes of death in patients with tetanus are associated with hypoxia, pneumonia, respiratory spasm, oversedation, exhaustion, shock, and secondary infection. Death from these causes often occurs in the first two to five days. More subtle and often delayed lethal factors are concerned with acidosis, alkalosis, and other electrolyte or enzymatic disturbances. Frequently patients who seem to be improving, insofar as the neuromuscular symptoms of the disease are concerned, may develop cardiorespiratory arrhythmias and high temperatures. This is particularly so in patients with heroin addiction who often die with a syndrome simulating central bulbar involvement. For patients who survive the first week, the prognosis for recovery is good. They generally improve

gradually but may have residual stiffness for two to six weeks in the muscles of the back, neck, and pelvic and shoulder girdles.

General Management

Due to the many factors involved, the clinical care of the patient with tetanus must embrace several phases. (A more extensive description of the routine treatment of tetanus[6] at the Cook County Hospital is the subject of a separate paper.) This includes the administration of tetanus antitoxin to neutralize circulating toxin; the use of penicillin and other antibiotics for secondary infections; the control of hyperirritability by sedation; the use of oxygen and tracheotomy to maintain respiratory adequacy; steroids for shock; the insulation of the patient from noises, bright lights, or other triggering stimuli; and general hygienic measures.

Tracheotomy has proved to be an important portion of therapy and in itself has been responsible for a reduction in the mortality due to tetanus. Its effectiveness depends not only on maintenance of a free airway but also on reduction of the apprehension and air hunger of patients with respiratory spasms.

Control of Spasms by Drugs

The control and prevention of seizures in patients with tetanus has been one of the most important and vexing problems. The general therapeutic procedures enumerated above fall short of attaining this goal. Drugs and other specific measures hitherto employed to control spasms have been of only moderate benefit and have introduced some additional hazards.

Management of the convulsive phase by sedative drugs has left much to be desired, since barbiturates and similar centrally acting sedatives must often be given to the point of respiratory depression in order to be effective. Deep sedation not only keeps the patient in a state of perpetual coma, thus preventing him from being communicative, but also increases the nursing problems because of the tendency for hypostatic pneumonia and lethal depression of respiration to occur.

From a theoretical point of view, muscle relaxants such as curare and its analogues were promising. Practically, however, they have proved to be ineffective in reducing mortality and morbidity. Curariform drugs, moreover, must be given parenterally. When injected intramuscularly in long-acting wax menstruums, they are ineffective, and therefore the aqueous forms must be given by continuous intravenous drip and to the point of respiratory paralysis. The use of the "iron lung" or of positive-pressure machines for artificial respiration adds not only tremendous obstacles to adequate nursing but also the hazards of the pulmonary complications due to the continued use of such machines. Curare, moreover, does not decrease the apprehension of the patient in spite of adequate oxygenation unless sedatives are simultaneously administered.

Mephenesin, because of its pharmacological action as a muscle relaxant in animals, has been tried and its use discontinued because of practical objections. It has an extremely short duration of effective action and must also be given by continuous intravenous drip and in very large doses. The clinical response of the patient has been disappointing and its effect on mortality and morbidity negligible.

Recently, chlorpromazine and its analogues were added to the list of drugs used to control the spasms of tetanus, and these drugs have been of some value. Chlorpromazine has not, however, successfully controlled seizures unless given to a point of putting the patient to sleep. If it is given for several days, a dangerous depression and fall of blood pressure may ensue. Although the drug has been responsible for giving some comfort to the patient, the side-effects such as hypotension and depression have militated against routine prolonged use in large doses, and it apparently has had no effect on the ultimate outcome of the disease. An advantage of the use of chlorpromazine is that somewhat smaller doses of barbiturates can be given.

In search for a drug which could be used with the assurance of a relatively wide degree of safety and which would control seizures without affecting respiration, blood pressure, or consciousness, we had occasion to use meprobamate (Miltown) intramuscularly. As a muscle relaxant, meprobamate, as compared to mephenesin and curare, has prolonged action. Its effectiveness in safe dosages has been reported by many authors. Our clinical experience with meprobamate in tetanus is presented not only to point out the remarkable effectiveness of the drug on some of the spasms of tetanus but also because our observations may help to elucidate the pathological physiology of tetanus and the pharmacological action of meprobamate.

Present Study

Patient Population.—At the pediatric division of the Cook County Hospital, a tetanus team has existed since 1933. All patients with tetanus coming to Cook County Hospital, whether children or adults, are referred to this service.

While tetanus formerly occurred mainly in children, most patients now are adults with heroin addiction. Of the 39 patients with tetanus treated with meprobamate in the 20 months prior to this writing, 20 were heroin addicts and 19 were nonaddicts. Of these, 14 (70%) addicts and 4 (21%) nonaddicts died (see table). All were adults, except for four children, the youngest being 6 months old, in the nonaddict group. There were no patients with tetanus neonatorum. Because of their debilitation and generally poor nutritional status, heroin addicts with tetanus are very poor risks, responding poorly to all forms of treatment.

Dosage.—Meprobamate was supplied in ampuls containing 400 mg. in 5 cc. of polyethylene glycol. The relative insolubility of the drug in conventional solvents has made it necessary for it to be supplied in this form. The drug must be given intramuscularly, since polyethylene glycol may cause a phlebitis if given intravenously. The dosage employed was 400 mg. every three to four hours for an adult, with relatively less for children. In spite of the fact that 5 cc. is a rather large intramuscular dose, we were surprised to find that it was relatively painless due to the local anesthetic properties of meprobamate.

Results.—Our experience with intramuscularly given meprobamate in the control of tetanus spasms has been so remarkable that we consider the drug to be the most valuable one currently available in the management of tetanus. The specificity of the drug in controlling only those spasms triggered by somatic stimuli has been surprising and somewhat difficult to explain.

Report of Cases

Our first experiences with the use of meprobamate in tetanus were so striking that our first two cases are herewith reported in detail.

CASE 1.—A 30-year-old woman, a known heroin addict, was admitted to Cook County Hospital with stiffness of the back and neck of six hours' duration. Although no objective evidence of tetanus (e. g., nuchal rigidity, trismus, or pathological reflexes) was present, the patient was given 20,000 units of tetanus antitoxin; 1,200,000 units of procaine penicillin G, intramuscularly; and methadone (Dolophine) hydrochloride, 10 mg. intramuscularly every six hours, for control of withdrawal symptoms. Within 12 hours after admission, she developed a stiff neck, increased deep tendon reflexes, abdominal rigidity, and difficulty in opening the mouth. The diagnosis of tetanus was made and the patient transferred to the tetanus service, where a tracheotomy was performed, another 80,000 units of tetanus antitoxin given, and a Levin tube passed. (In narcotic addicts with skin infections, cut-downs for intravenous injections are avoided where possible because of the difficulty in finding veins and the danger of infection.)

Within 24 hours after the onset of the first symptoms, the patient was having generalized spasms. This rapid onset of spasms indicated a grave prognosis. Pentobarbital, 2 grains (125 mg.), and chlorpromazine, 50 mg., were given intramuscularly every four hours. Chlorpromazine was used primarily as a tranquilizer and as a potentiator of barbiturate action.

The patient became rapidly worse, and within 12 hours after onset the seizures were more severe, occurring every few minutes, and management became more difficult. Seizures were precipitated by the slightest noise, by moving the patient, or by attempting to aspirate the tracheotomy tube. It was obvious that a marked increase in dosage of pentobarbital and/or chlorpromazine would be necessary to attain any degree of control of these seizures. Feeling that the patient's rapid course and bad prognosis justified the use of any measures which might offer promise of help, an intramuscular injection of 400 mg. of meprobamate in 5 cc. of polyethylene glycol was administered.

Within 10 minutes dramatic improvement was noted. Not only did the seizures cease but the patient became relaxed; the trismus, as well as the abdominal rigidity and lordosis, disappeared. To our surprise, loud noises or bright lights did not precipitate spasms. We were amazed to find that the patient could be stuck with a pin without precipitating a spasm. This observation was unique in our experience with tetanus, particularly because the patient was not comatose and could respond to simple commands. At this point, an attempt was made to aspirate the tracheotomy tube and the patient had a generalized spasm. Seizures could also be precipitated by gagging the patient with a tongue depressor or by passing a catheter into the bladder. In spite of the fact that somatic stimuli failed to evoke seizures, "spontaneous" spasms were frequently observed. It soon became obvious that these "spontaneous" seizures were associated with evidence of visceral discomfort such as cough, colic, or a plug in the tracheotomy tube. Further observation disclosed that spasms were also precipitated by proprioceptive stimuli from passive movement of a hip or shoulder in turning the patient. In spite of the fact that meprobamate given intramuscularly every three to four hours controlled many of the severe seizures and apparently all of those usually precipitated by noise or other somatic stimuli, the patient's condition continued to deteriorate. Within 48 hours her temperature rose from 100 to 104 F (37.8 to 40.0 C) rectally, her pulse rate increased to 130 per minute and became irregular, and her respiration rate increased to 40 per minute and became irregular and of the Biot type. The patient lapsed into coma and died on the fifth day after admission.

It was of interest to note that while on meprobamate therapy this patient received only 6 to 9 grains (390 to 580 mg.) of pentobarbital every 24 hours as compared to the 18 to 24 grains (1,160 to 1,550 mg.) of this drug usually necessary to sedate other heroin addicts who have tetanus.

Comment.—Our experience with meprobamate in our first patient with tetanus induced us to continue the use of this drug in our next one. Our second patient, who recovered, convinced us that the amazing effect of meprobamate on spasms noted in the first patient was not simply a fortuitous circumstance but represented a remarkable pharmacological effect.

CASE 2.—A 20-year-old man, a nonaddict, had crushed his left thumb in an automobile door nine days before the onset of his first symptoms, which consisted of a mild backache and stiffness of the neck. Within 48 hours he was admitted to the hospital with a full-blown case of tetanus. On admission, he was in acute distress with severe pain in the neck and back, abdominal rigidity, opisthotonus, and generalized spasms every two to three minutes. He was unable to open his mouth more than 0.5 cm. Deep tendon reflexes were hyperactive, and attempts to elicit these responses resulted in convulsive spasms. The temperature was 101 F (38.3 C) rectally, and all over vital signs were normal. Because of the rapid onset of seizures (less than 48 hours after the first symptom) a guarded prognosis was given. A tracheotomy was performed, penicillin therapy started, 80,000 units of tetanus antitoxin administered, the wound débrided, and a Levin tube passed to facilitate feeding. Because of a distended bladder, a retention urethral catheter was inserted.

Since at this time we did not have full confidence that meprobamate alone would effectively control spasms, the patient was first given 3 grains (194 mg.) of pentobarbital and 10 mg. of chlorpromazine intramuscularly; he was then started on therapy with meprobamate, 400 mg. intramuscularly every four hours. This patient did so remarkably well on meprobamate therapy that chlorpromazine was withdrawn and pentobarbital dosage cut to 1.5 grains (97 mg.) intramuscularly occasionally for sleep and control of pain. As in the first patient, within 10 minutes after the injection of meprobamate the spasms ceased entirely. The patient became relaxed and his trismus disappeared; he could now open his mouth to a width of 2.5 cm. He was communicative and responded to commands. Although pinprick, noises, or sudden sprinkling with cold water did not precipitate a seizure, light visceral stimuli such as passing a catheter into the tracheotomy tube did so. In fact endogenous visceral stimuli precipitated "spontaneous" spasms.

Because the patient was conscious and communicative, it was possible to discover some of his visceral complaints and to correct some of them. For instance, when he was having a series of spasms for no apparent somatic reason, he complained of the catheter in his bladder. When asked if he would rather have the nasal or the bladder catheter removed, he vehemently indicated the latter. After this was removed, all of his spasms ceased except hose caused by aspirating the tracheotomy tube or turning him in bed. On another occasion, when began to get spontaneous spasms, the removal of a fecal impaction was followed by their cessation. A distended bladder or intestine would often be associated with spasms.

Even during the most severe period of the illness, spasms were adequately controlled by meprobamate alone with very little pentobarbital. Patients treated previously without meprobamate required as much 18 to 24 grains of pentobarbital in a 24-hour period and, even with this, had only a fair control of spasms; moreover, these patients remained continually stuporous, and the danger of respiratory depression was constantly present. The present patient received a maximum of 6 grains and an average of 3 grains of pentobarbital in any 24-hour period for the first 10 days. Thereafter, his maximal daily dose was only 3 grains with an average of 1.5 grains. At the end of the second [illegible] the tracheotomy tube was removed; at the e[illegible] fifth week the patient was discharged as c[illegible] with some residual stiffness in his muscles.

Comment.—The experience [illegible] in these two cases was repeated and reaffirme[illegible] remaining series of 39 patients. Not only we[illegible]s adequately controlled by meprobamate a[illegible] ven between spasms the patient was more r[illegible] trismus, risus sardonicus, abdominal rig[illegible] arched back disappeared or were markedly le[illegible]. The mouth could be opened wider and the [illegible] could be passively flexed through a much wi[illegible] range.

In practically all instances the onset of drug effectiveness was within 10 to 15 minutes and the duration of effectiveness was 3 to 4 hours. In most patients, complete control of somatically induced seizures was attained by giving 400 mg. of meprobamate in 5 cc. of polyethylene glycol intramuscularly every four hours. By injection, the drug was much more effective than 10 times this dose given orally. It was not possible to contral spasms completely during the acute phase of the disease with as much as 5,600 mg. (14 tablets) of meprobamate in a single orally given dose in two patients in whom this large dose was tried. In convalescent patients or those with relatively mild involvement, however, it was frequently possible to control discomfort and residual local muscle spasm by the oral administration of 800 mg. of meprobamate four times per day. To rule out the possibility that the beneficial effects of the injectable medicament were due to the vehicle, controlled injections of 5 cc. of polyethylene glycol alone were used, without any therapeutic benefit.

In addition to controlling somatically induced spasms, meprobamate had a tranquilizing action which allayed apprehension and made the patient generally more calm and comfortable. Nurs[illegible] greatly simplified. The patients were consci[illegible] communicative, could respond to simple com[illegible] and could make their needs known. It was no[illegible] necessary to insulate the r[illegible] against nois light. Tracheotomy, which had been routinely done in all patients with tetanus, regardless of cause or severity, was now made an elective procedure in the nonaddicts and actually was not done in 6 of the 19 patients in this group.

Effect on Mortality

Since morbidity was so greatly reduced by use of meprobamate, it was of interest to note whether [illegible] not these benefits were reflected in a re[illegible]ced mortality. Our previous experience had in[illegible]cated that drug therapy, even when it controll[illegible] spasms, generally had no effect on mortality. Ei[illegible]teen (46%) of the 39 patients in this series died[illegible] The mortality among the addicts was 70% as [illegible]pared to 21% among the nonaddicts.

The table compares the [illegible]lity in the meprobamate-treated group [illegible] [illegible] that in a previous group treate[illegible] [illegible] other methods. In the 51-month period, [illegible] 1, 1954, to Dec. 1, 1958, there were a total of 90 tetanus patients treated at Cook County Hospital, with 51 deaths, or a mortality of 58%.

Comparative Mo[illegible] in Patients With Tetanus With and out Use of Meprobamate

	Without Meprobamate			With Meprobamate		
	Patients, No.	Died No.	Died %	Patients, No.	Died No.	Died %
[illegible]	36	26	73	20	14	70
[illegible]dicts	15	7	47	19	4	21
[illegible]tal	51	33	65	39	18	46
Onset of Spasms Before 48 Hr.						
Addicts	26	20	80	14	13	93
Nonaddicts	8	5	63	8	3	38
Total	34	25	73	22	16	73
Onset of Spasms After 48 Hr.						
Addicts	4	1	25	6	1	17
Nonaddicts	4	1	25	11	1	9
Total	8	2	25	17	2	12

The treatment of all these patients was similar, except for the drugs used in the control of seizures. All of the patients, except for six in the meprobamate-treated group, were tracheotomized. For the first 31 months of this period, there were 51 patients treated with tribromoethanol (Avertin) and pentobarbital as the main sedative drugs. In 15 of these curarization and artificial respiration had also been used, and in 20 chlorpromazine had also been used. Since there was no appreciable difference in mortality or morbidity in any group in which different treament combinations were used, these are treated as a single group for comparison with the meprobamate-treated group of 39 patients which is the subject of this report.

In the group treated without meprobamate, 65% [illegible]1 patients died as compared to 46% of the [illegible]ents in the meprobamate-treated group—a [illegible] but not remarkable reduction in mortaliy. [illegible] the patients, however, are grouped as addicts [illegible] mortality r[illegible]nained the same—about 70% regardless of type [illegible] treatment used. This is not surprising, since [illegible]ese patients have not only the most severe typ[illegible]f tetanus with rapid onset of seizures and with [illegible]bar involvement but also a considerable degree [illegible] physical and nutritional debility. The cause of death in the heroin addicts with tetanus appears generally not to be tetanus per se but rather some other intercurrent, as yet unidentified, lethal factor. In the nonaddicts with tetanus, however, 7 (47%) of fifteen died before meprobamate was used, and only 4 (21%) of 19 treated with meprobamate died—a reduction in mortality of over 50%.

In order to rule out the possibility that this improvement in mortality in the nonaddict group was fortuitous [illegible] due, perhaps, to the fact that patients with milder cases of tetanus were being treated in the meprobamate series, the group was subdivided into those with a rapid onset of spasms, less than 48 hours, and those with a slower onset, over 48 hours from the appearance of the first symptoms. As previously pointed out, the mortality and severity of tetanus of all types is closely related to the interval between the appearance of the first symptom and the onset of spasms. The shorter this interval of onset, the worse is the prognosis.

From the table it is seen that in addicts with a seizure onset interval under 48 hours, the mortality was always high, from 80% to 93%, regardless of the method of treatment. For the nonaddicts, on the other hand, with onset of spasms less than 48 hours, there was a decrease in mortality from five (63%) of eight in patients not given meprobamate to three (38%) of eight in those on therapy wit meprobamate. Although the number of cases i each of these categories is too small to be o statistical significance, gross inspection indicates trend toward decreasing mortality with meprobamate treatment. The lower mortality in nonaddict as compared to addicts is in part due to the fac that most of the addicts had an onset period of less than 24 hours while most of the nonaddicts in the rapid onset group had onset intervals between 24 and 48 hours.

When the period of onset of seizures is over 48 hours, the mortality is much less (under 25%), regardless of whether the patient is an addict or not. Even in this group with milder cases of tetanus the mortality was less for those on meprobamate therapy (two deaths in 17 patients) than for those who were not given meprobamate (two deaths in 6 patients). It would thus appear that both morbidity and mortality are decreased when tetanus patients are treated with meprobamate, with the exception of heroin addicts with severe tetanus and with rapid onset of seizures.

The fact that the patient treated with meprobamate is more communicative has simplified nursin and has made it possible to discover some of th

What is more difficult to explain, however, is the observation that meprobamate seems to stop only somatically induced spasms, having no effect on those induced by visceral or proprioceptive stimuli (fig. 2C). No information is available as to whether or not meprobamate will protect animals against strychnine seizures evoked by visceral stimulation. In any event, the apparent selective action of meprobamate in preventing only exteroceptively induced tetanus seizures makes one postulate that the site of action of this drug is somewhere in the ascending tracts of the exteroceptive pathways. To our knowledge, no drug has heretofore been found which has such a highly selective action. Experimental studies in animals with strychnine seizures might help to elucidate this rather unique effect.

Some studies in humans, however, have corroborated the selective action of meprobamate on exteroceptive pathways. Nyquist and associates[10] studied the comparative effect of meprobamate, zoxazolamine (Flexin), phenobarbital, and placebos on patients with spinal cord injuries. They found that meprobamate was the most effective drug in relieving spasticity in the skeletal musculature. They were surprised to find, however, that it had relatively little effect on bladder and sphincter musculature in cystometric studies. Although, clinically, in some of their patients a catheter became unnecessary during meprobamate therapy, the effect of the drug on the bladder and vesical neck was equivocal. In other words, these authors also discovered that, whereas meprobamate would decrease spasticity and irradiated responses to somatic stimuli, it apparently had no effect on bladder muscles in response to stimuli elicited from the bladder.

Holliday[11] studied the effect of meprobamate, chlorpromazine, pentobarbital, and a placebo on the disrupting effect of stress on trained performance. The stimuli used in causing the stress were al exteroceptive, and meprobamate was the only d found to have a beneficial effect. The author in not employ proprioceptive or visceral sti ulate their study, but it would be of interest to s proba- as to whether the beneficial effect from visceral mate they observed would be duplicat or proprioceptive stimuli had been u

tracheotomy are concerned. Morbidity has been greatly reduced. Mortality also has been greatly reduced in nonaddicted patients and in addicts with slow onset of spasms (over 48 hours). It has not appreciably reduced the mortality of heroin addicts with tetanus whose spasms generally occur within 24 hours after onset of symptoms, although it has reduced their morbidity and simplified their nursing care. The drug has been found to be safe and harmless and to date is the most effective drug for the control of somatically evoked spasms of tetanus.

4743 N. Drake Ave. (25).

The meprobamate ampuls used in this study were supplied through Dr. Frank Berger, Wallace Laboratories, New Brunswick, N. J., for experimental trial in reducing spasticity and hypertonus in patients with cerebral palsy.

This study was aided in part by grants from the Muscular Dystrophy Association, Chicago Chapter; United Cerebral Palsy Association of Chicago, Inc.; and Wallace Laboratories, New Brunswick, N. J.

HYPERURICEMIA—RELATIONSHIP TO HYPERCHOLESTEREMIA AND ACUTE MYOCARDIAL INFARCTION

Paul M. Kohn, M.D.
and
George B. Prozan, M.D., Cleveland

Hyperuricemia appears to be a concomitant of myocardial infarction with practically the same degree of frequency as hypercholesteremia. In a group of 35 men studied, 79% manifested serum uric acid levels above 6 mg. per 100 ml. It is recommended that, in assessing the proneness of a person to coronary heart disease, the uric acid level be considered, in addition to the cholesterol or other serum lipid levels, family history, and other factors. It is also advisable to use probenecid prophylactically in such patients.

The high incidence of arteriosclerosis as a complication of gout has been well known for over 50 years,[1] but the question of the more specific relationship of hyperuricemia to coronary artery disease has been raised comparatively recently. Gertler and associates[2] were the first to note a statistically significant incidence of hyperuricemia in a group of patients with coronary heart disease. They reported that, in 92 males who had experienced myocardial infarction prior to the age of 40 years, 24% had serum uric acid levels above 6 mg. per 100 ml. whereas only 6% of a matched control group and 6% of a larger group of unselected controls had a similar degree of hyperuricemia. Actually, hyperuricemia has been defined by some authors as being a level above 5 mg. per 100 ml., and on this basis Gertler and associates found that 48% of the patients with infarct had hyperuricemia, compared with 42% in the matched control group and 31% in the unselected control group.

Although they gave no figures, Dreyfuss and Czaczkes[3] mentioned that the incidence of hyperuricemia in their group of patients with coronary disease was "by no means negligible."

The present study was undertaken to further clarify the apparent association between hyperuricemia and coronary artery disease, as well as that between these two entities and hypercholesteremia. Basically the method utilized by us consisted of determining the serum uric acid and cholesterol levels in a relatively unselected group of patients admitted consecutively to a general hospital with a verified diagnosis of acute myocardial infarction. No control group was included in this study, inasmuch as we felt that it is practically impossible to determine the presence or absence or degree of coronary atherosclerosis in any given person prior to the appearance of overt coronary disease as manifested by myocardial infarction or by recognizable angina pectoris.

Methods

Fifty consecutive patients admitted to the Mt. Sinai Hospital, Cleveland, with a verified diagnosis of acute myocardial infarction were selected for study. Patients above 70 years of age were rejected from this series because of the frequent association of complications, debility, and other diseases. Diabetic patients were likewise omitted because of hypercholesteremia attributable to the diabetic state per se. In addition, all patients who died less than 48 hours after admission were also excluded.

The diagnosis of myocardial infarction in all cases was confirmed by the typical electrocardiographic changes, as well as by elevated serum glutamic oxalacetic transaminase levels. Serum uric acid and cholesterol levels were determined in each patient shortly after admission and in most patients and subsequent intervals during the course of their hospitalization.

The uric acid level was determined by the phosphotungstate–sodium cyanide method of Brown. The standard method of Bloor was used for determination of the serum cholesterol level.

Results

Tables 1 and 2 summarize the pertinent data in 35 male and 15 female patients. The order of listing and numbering of the patients has been arbitrarily arranged according to age, rather than by date of admission. In the male group 5 were between 31 and 39 years of age, 7 were between 40 and 49, 8 were between 50 and 59, and 15 were between 60 and 69. The youngest female study was 49 years of age, and an equal were in the sixth and se of the patients

levels over 5 mg. per 100 ml. In the group with uric acid levels above 6 mg. per 100 ml., 15 of the 19 patients under 60 years of age were in this definitely hyperuricemic category. The three males in our series who had normal uric acid levels were all over 60 years of age. The average serum uric acid level of the entire group of males was 6.5 mg. per 100 ml., and the average value in those below the age of 60 years was 7.2 mg. per 100 ml.

Comment

There is relatively wide acceptance today of the concept of the relationship between hypercholesteremia and coronary heart disease, and increasing numbers of students of the subject are willing to assign a pathogenic role to this lipid in the development of coronary artery sclerosis. One reason for considering cholesterol as an etiological agent is the almost universal finding of elevated serum cholesterol levels in patients with proved coronary artery disease. In a study of nearly 5,000 healthy men 40 to 59 years of age, over a period of two years 32 developed myocardial infarction and 86% of these had had excessively high cholesterol levels at the beginning of the study.[4]

Our results also amply illustrate the almost necessary correlation between elevated serum cholesterol levels and coronary artery disease; in our series 43 of the 50 patients had levels above 250 mg. per 100 ml. It was our impression that the stress incident to the acute myocardial infarction itself plus the emotional trauma produced by admission to a hospital caused relatively little if any further increase in cholesterol levels, for we found that in one-half the cases the admission cholesterol level was not higher than that in subsequent determinations. The logical consequences of this apparent but as yet not wholly proved role of hypercholesteremia in the development of coronary artery disease are (1) the use of the cholesterol level in predicting proneness to coronary disease and (2) the attempt to prevent premature development and/or further progress of coronary atherosclerosis by reducing serum cholesterol levels by means of dietary management and drugs.

50	70	336	280	7.6

As found in our study, hyperuricemia also appe
to be a concomitant of myocardial infarction
practically the same degree of frequency as h
cholesteremia. In our series, in the group
below the age of 60—the so-called premat
nary group—this fact was particularly s
% of these patients manifested ser

levels over 6 mg. per 100 ml. Further emphasizing the significance of this finding is the fact that in reports of groups with neither gout nor coronary disease those patients with serum uric acid levels above 6 mg. per 100 ml. comprised only from 3 to 17% of the total.[5]

Although at present this relationship is not widely appreciated, at least one other group of investigators is impressed with the potential significance of hyperuricemia in the coronary problem. Gertler and associates [2] have incorporated the uric acid level in their so-called CUP ratio: K equals cholesterol level (mg.%) multiplied by uric acid level (mg.%) and divided by phospholipid level (mg%). This is used in assessing the proneness to coronary heart disease of a given person, and, thus, these workers recognize that the higher the uric acid level, just as the higher the serum cholesterol level, the greater is the probability that coronary artery disease will eventuate.

Although our results clearly demonstrate the extremely frequent coexistence of hyperuricemia and coronary artery disease, the explanation for this association is not obvious. It is known that hyperuricemia is inherited as a simple Mendelian dominant characteristic,[6] as is hypercholesteremia.[7] Heredity or genetic predisposition has been considered to be a most significant factor in the development of coronary artery disease itself.[8] One might then speculate as to the genetic linkage of these three traits, i.e., hyperuricemia, hypercholesteremia, and coronary disease. In this connection it is noteworthy that, whereas Gertler and associates [2] found that 48% of their patients with myocardial infarction had hyperuricemia, in our series almost twice as high an incidence was found. One feature of our series that is presumably somewhat different is the high percentage of Jewish patients in our hospital. Inasmuch as this group is extremely inbred, it would appear that a hereditary defect, such as hyperuricemia and, for that matter, hypercholesteremia, would tend to be disproportionately high in incidence.

Regardless of the explanation for the association of hyperuricemia and coronary artery disease, the predictive value of this parameter seems apparent. Of greater importance is the question of what part, if any, uric acid plays in the pathogenesis of coronary atherosclerosis. Here again little is known of the role played by uric acid in the development of vascular disease. Traut and co-workers [9] demon-
ated deposits of urate crystals in the proliferated
ma of arteries or in organized thrombi, and this,
urse, represents one mechanism by which uric
may participate in the process of vascular
tion. Another possible factor is that uric
surface-active agent and may facilitate
n of lipids in the subintimal tissues of
vessels.

It would appear that more investigative work along these lines is indicated for the elucidation of the role of uric acid in coronary artery disease. This is particularly important since there is already available a most satisfactory uricosuric agent for the control of elevated serum uric acid levels, namely, probenecid. We feel that consideration should be given to the possible benefits to be derived from the administration of this drug to patients with hyperuricemia, even in the absence of clinical gout. This particularly applies to those patients who also have elevated cholesterol levels and family histories of coronary artery disease, for if it should ultimately be established that elevated serum uric acid levels promote and facilitate the development of coronary atherosclerosis, a certain amount of "protection" may thereby be afforded. Along these lines, mention should be made of the uricosuric action of the coumarin compounds, inasmuch as the possible benefits of anticoagulant therapy with these agents, in both short-term and long-term therapy, on coronary artery disease ha been ascribed by some investigators to the reduction in serum uric acid levels produced by thes drugs.[10]

Summary

Serum uric acid and cholesterol level determin
tions were made on 50 consecutive patients wit
acute myocardial infarction, including 35 men ar
15 women. Twenty of the men and six of the wome
had serum uric acid levels above 6 mg.%
men and 10 women had levels a
Forty-three of the 50 patients had serum cholester
levels above 250 mg.%. Only one man and o
woman had normal levels of both uric acid a
cholesterol.

Because of the high incidence of hyperuricem
in association with myocardial infarction, it is r
ommended that the uric acid level be conside
in assessing the proneness of a person to coron
heart disease, along with the cholesterol or ot
serum lipid levels, family history, and other fact
It is also advisable to use probenecid prophy
tically in persons with hyperuricemia, particul
in those with hypercholesteremia and genetic
stitutions indicating proneness to coronary h
disease.

HEMOGLOBINURIA AFTER MASSIVE INTRAPERITONEAL HEMORRHAGE

Jay N. Cohn, M.D.
and
Elliot L. Sagall, M.D., Boston

Determination of plasma hemoglobin levels may be a useful clinical tool for detection of bloody serous effusions when direct aspiration cannot be carried out successfully. After such extravasation, there is usually rapid absorption of unchanged blood cells through the diaphragmatic peritoneum, with return to the general circulation through mediastinal and parasternal lymphatics. Any delay in this absorption process would probably increase the degree of hemolysis. In this patient, massive hemolysis occurred. Factors probably responsible included excessive load on the lymphatic system, extreme abdominal distention, and pulmonary edema causing engorgement of the right lymphatic duct, with delayed appearance of hemoglobinemia and hemoglobinuria.

he appearance of free hemoglobin in the plasma urine after intraperitoneal hemorrhage is a henomenon which has not received much attenion in recent medical literature, although its use diagnostic sign was described over 20 years go. 28

The following case of massive hemoglobinuria is eported because it reemphasizes the need for wareness that red blood cells and hemoglobin can e absorbed intact through serosal surfaces.

Report of a Case

A 31-year-old woman was transferred to Beth rael Hospital, Boston, on Feb. 9, 1958, for evaluaon of persistent blood loss postoperatively. The tient had a history of nine pregnancies, the first o resulting in normal full-term spontaneous deries but the remaining seven ending prematurefive because of spontaneous abortions in the rth to fifth month of gestation and two with arean sections in the sixth month for stillborn uses. There was no history of bleeding tendency of anemia, and she had otherwise been in good lth.

n Jan. 29, 1958, 11 days prior to her transfer to Beth Israel Hospital, a four-and-one-halfth pregnancy terminated in spontaneous abor. The placenta was retained, and the next day as removed by dilation and curettage at another hospital. She was well until Feb. 7, two days prior to transfer, when vaginal hemorrhage suddenly occurred. She was readmitted to the other hospital in shock, with pulse rapid and thready and blood pressure unobtainable. Examination revealed retained placental fragments. Because uterine packing was unsuccessful in stopping the flow of blood, a supracervical hysterectomy was performed with the patient under general anesthesia. The surgeons

---

ice, Beth Israel Hospital, and the Department mari School. Dr. Cohn is now Senior Assistant barbiturvice Hospital, Galveston, Texas.

noted that the uterine attachments were friable, particularly on the right side where more sutures than usual were required to establish hemostasis.

Two units (1,000 cc.) of whole citrated blood was given before and during operation, and blood pressure was maintained at 120/80 mm. Hg. Estimated blood loss during the operation was 500 cc. Postoperatively she again went into shock, and over the course of the next 48 hours she received intravenously 8 more units of whole blood in addition to levarterenol, 1,000 cc. of isotonic sodium chloride solution, 2,000 cc. of sodium lactate solution, 3,000 cc. of dextrose and water, 2 Gm. of tetracycline, and 300 mg. of hydrocortisone. Despite the 10 units of blood, her hematocrit value stayed below the admission level of 30%. There was no sign of external bleeding; the wound remained clean; and no abdominal fluid wave was demonstrable. Eight units of blood used in transfusion had been compatible, A positive, while 2 units had been A negative.

On the second postoperative day tachypnea and facial edema were noted. Her hematocrit value was 30% and hemoglobin level 70%. She was transferred to the Beth Israel Hospital for further study. On admission she was pale and cyanotic and had marked tachypnea. The temperature was 99 F (37.2 C) rectally, the pulse rate 120 per minute and regular, the respiratory rate 48 per minute, and the blood pressure 110/60 mm. Hg. The neck veins were markedly distended and pulsating above the angle of the jaw. There were dulness and absent breath sounds at the base of the right lung, but the lungs were otherwise clear to auscultation. The left border of cardiac dulness was percussed at the midclavicular line in the fifth interspace. No murmurs were heard. The abdomen was distended, with dulness in the flanks, slight shifting dulness, but no definite fluid wave. The intestinal sounds were diminished. The suprapubic operative incision was healing normally. There were no ecchymotic areas and no evidence of bleeding diathesis. The skin was sallow but not icteric.

Urine findings were within normal limits. Examination of the blood revealed a hemoglobin level of 10 Gm. per 100 ml., hematocrit value 30%, and white blood cell count 12,000 per cubic millimeter, with 85% neutrophils. The clotting time, platelet count, fibrinogen titer, osmotic fragility test result, and Coombs' test result were all within normal limits. The serum sodium level was 141 mEq. per liter, potassium 3.0, chloride 103, and carbon dioxide 35. Prothrombin content was 65%, and prothrombin consumption was normal. Result of an Aschheim-Zondek test was negative. Stools were negative for occult blood. Cultures of the urine and blood were negative. A chest x-ray on admission showed findings consistent with massive pulmonary edema and a right pleural effusion. Roentgenogram of the abdomen revealed air in the small intestine consistent with an ileus. An electrocardiogram showed T-wave changes consistent with hypokalemia.

Because of the admission impression of possible intraperitoneal hemorrhage, a diagnostic abdominal tap was performed in the right lower quadrant. However, no free fluid or blood was obtained. The pulmonary edema was thought to be due to hypervolemia from circulatory overloading with sodium-containing fluids and steroids during the postoperative period. She was treated with a low-sodium diet and mercurial diuretics. On the third hospital day, because of persistent respiratory distress, bilateral thoracenteses were performed, yielding 400 cc. on the right and 40 cc. on the left of grossly bloody fluid. By the next day venous distention had disappeared and the lungs had cleared.

On the fourth hospital day her urine was noted to be red and her serum darkly colored. The serum bilirubin level was 2.2 mg. per 100 ml., and the blood hemoglobin level, which had been stable, showed a precipitous increase from 10.8 to 12.5 Gm. per 100 ml. A reticulocyte count was 7.9% (see table). Spectroscopic examination of the serum showed the absorption bands typical of oxyhemoglobin and methemalbumin. Results of repeat Coombs' test, indirect Coombs' test against minor antigens, and tests for hemolysis in cold or acid were all negative. Repeat right thoracentesis yielded 20 cc. of grossly hemolyzed blood. Abdominal paracentesis in the left lower quadrant was productive of a small amount of gross blood with a hematocrit value of 13%. Spectroscopic examination of the plasma from this specimen showed the bands of oxyhemoglobin only. Quantitative hemoglobin determination on this plasma by the benzidine method of Bing and Baker (cited by Ham[2]) was 1,240 mg. per 100 ml. (normal plasma contains less than 5 mg. per 100 ml. by this method).

Massive hemoglobinuria with black urine persisted for six days. Significant elevation of the plasma hemoglobin level was detected for 10 days and probably persisted for much longer. A maximum plasma concentration of 633 mg. per 100 ml. was observed on the 6th hospital day, and a level of 45 mg. per 100 ml. was still present on the 13th day, the last day on which quantitative determinations were done.

Throughout the first three weeks of hospitalization, the patient persistently had a temperature of up to 102 F (38.8 C) and moderate abdominal distention. A mass gradually became prominent in the right lower quadrant, and x-rays of the abdomen showed evidence of incomplete obstruction of the small intestine. However, she was able to take food orally and had regular bowel movements. The mass became palpable rectally, and on the 18th hospital day culdotomy was performed with the hope of evacuating it vaginally. Aspiration, however, produced only 10 cc. of hemolyzed, dark brown blood which was sterile on culture. Because it was felt that loculation of the blood had occurred, no further attempts at evacuation were made.

Over the course of the next week her temperature returned to normal, her appetite improved, she gained weight, the abdominal mass became smaller, and her hemoglobin level remained stable. She was discharged on the 28th hospital day to complete her convalescence at home.

Comment

The complete absorption of intact red blood cells placed in the peritoneal cavity has been repeatedly demonstrated by clinical observations as well as by experimental studies. Donor blood injected intraperitoneally in animals may disappear entirely within 24 hours, and elevations of the red blood cell count and hemoglobin concentrations in the circulating blood may be detected almost immediately.[3] Intraperitoneal transfusions of oxalated blood have been used in infants with satisfactory results.[4]

Studies with use of labeled red blood cells in animals[5] and human subjects[6] have demonstrated that absorption of intraperitoneal blood begins immediately; however, up to two weeks may be required for complete incorporation of this blood into the circulation. Absorbed red blood cells have a normal life span.[6b]

The mechanism of absorption from the serous cavities has been reviewed by Courtice and Simmonds.[7] Protein and cells are absorbed from the peritoneal cavity almost exclusively through the diaphragmatic peritoneum, passing into the circulation by way of the mediastinal and parasternal lymphatics, most of which empty into the right lymphatic duct. Absorption from the pleural cavity takes place through the lower mediastinal pleura and costal parietal pleura. The protein and cells then pass through the same lymphatic channels to drain into the right lymphatic duct. The discrepancy noted in the literature between the rapidity of disappearance of blood from the peritoneal cavity and the delay before all of it can be accounted for in the circulation may be due in part to the slow passage through the parasternal and mediastinal lymphatics.[6a] Indeed, Courtice and Simmonds[7] noted in animal studies that blood was occasionally extravasated into the pleural cavity from engorged parasternal lymphatics. This mechanism could explain the bloody pleural effusion found in the case reported here.

The amount of intraperitoneal blood which is hemolyzed prior to its absorption has not been well quantitated. Courtice and co-workers[8] studied the peritoneal reaction which follows the introduction of blood and noted that only a small percentage of the macrophages contained phagocytosed red blood cells. Although lymph nodes in the absorptive pathway did contain large numbers of macrophages engorged with red blood cells, these authors concluded that the actual number of cells lysed was extremely small in comparison to the number absorbed intact. However, apparently enough hemolysis may occur to produce detectable hemoglobinemia or hemoglobinuria from absorption of free hemoglobin. Two of the dogs studied by Hahn and associates[5] were noted to develop hemoglobinemia or gross hemoglobinuria after the introduction of blood into the peritoneal cavity. Pommerenke[1b] described three cases of ruptured ectopic pregnancies in patients in whom hemoglobinuria was demonstrable either grossly or spectroscopically.

Any delay in the usually rapid absorption after hemorrhage into a serous cavity would probably increase the degree of hemolysis by allowing more time for the macrophage system to lyse the cells prior to their return to the circulation. Blood which clots in a serous cavity is no longer absorbable as cellular elements and must be absorbed as hemoglobin and bile pigments. Pritchard and Adams[6b] placed radioactive chromium-labeled clottable blood and small clots into the peritoneal cavities of patients undergoing laparotomy and noted much less absorption than when citrated blood was introduced. They made no observation for hemoglobinuria or hemoglobinemia. Whereas small amounts of blood may be easily handled by the lymphatic system, in massive hemorrhage the lymphatics could become engorged, thus delaying the complete emptying of the serous cavity and probably increasing the amount of hemolysis. In addition, normal diaphragmatic movement plays an important part in peritoneal and pleural absorption by speeding lymphatic drainage and flow.[9] The presence of abdominal distention, ileus, and general inactivity which frequently accompany conditions associated with hemorrhage into a serous cavity would all tend to diminish diaphragmatic movement and further delay absorption.

In the patient presented in this report massive hemolysis did occur. Although it is possible that the blood was initially hemolyzed retroperitoneally and later ruptured into the peritoneal cavity, it is consistent with known physiological mechanisms to postulate that the unusual amount of hemolysis occurred within the peritoneum. The amount of clottable intraperitoneal blood, estimated to be about 3,500 cc. on the basis of transfusion requirements, was approximately equal to this woman's total blood volume. This quantity undoubtedly exceeded the absorptive capacity of the lymphatic system. The patient suffered from extreme abdominal distention, ileus, and partial intestinal obstruction during her hospitalization, thus further delaying the absorptive process. In addition, she had pulmonary edema during the first three hospital days. Pulmonary edema fluid is reabsorbed in large part by way of the lymphatics with ultimate drainage into the right lymphatic duct,[7] the same channel by which intraperitoneal and intrapleural blood returns to the circulation. The pulmonary edema fluid may have engorged the right lymphatic duct, further slowing the drainage from the peritoneal cavity and perhaps accounting for the delay in appearance of hemoglobinemia until the fourth hospital day.

Nonsurgical management of such a large collection of intraperitoneal blood is undoubtedly rare. However, small to moderate collections of bloody fluid in the pleural or peritoneal cavities are encountered in a wide variety of clinical situations. Some hemolysis must occur in all these bloody serous effusions, and the paucity of observations of hemoglobinemia and/or hemoglobinuria in these conditions may be due to a lack of awareness of the occurrence of this phenomenon. The presence in the circulation of the hemoglobin released by the lysis of only 5 cc. of blood would raise circulating plasma hemoglobin values to almost five times the normal value, a quantity easily recognizable by a simple colorimetric methods.[2] It is, therefore, suggested that determination of plasma hemoglobin levels may be a useful clinical tool for the detection of bloody serous effusions when direct aspiration cannot be carried out.

Summary

A case of massive hemoglobinuria occurred after postoperative intraperitoneal hemorrhage. Many physiological mechanisms may contribute to hemolysis of blood in a serous cavity. The determination of plasma hemoglobin levels may be used as a tool in the detection of intraperitoneal or intrapleural blood.

454 Brookline Ave. (15) (Dr. Sagall).

THERAPEUTIC IMPORTANCE OF ISONIAZID—The antituberculous effect of isoniazid is so great that its use is indicated in every case in which susceptible tubercle bacilli are found. In the absence of gross caseation and destruction the inclusion of other drugs adds little to the results achievable. In the presence of pulmonary cavitation, the therapeutic effect of isoniazid is enhanced about equally by daily streptomycin or PAS.—E. Rothstein, The Eighteenth Veterans Administration—Armed Forces Conference on the Chemotherapy of Tuberculosis, *The New England Journal of Medicine,* June 25, 1959.

PHENTOLAMINE HYDROCHLORIDE IN PREVENTION OF CUTANEOUS NECROSIS DUE TO LEVARTERENOL

A. Stephen Close, M.D., Wood, Wis.

> *It is reasonable to assume that the mechanism by which phentolamine reverses the ischemia associated with extravasation or tissue diffusion of levarterenol is through blockage of action by the latter on adrenergic effector cells. Accumulated evidence indicates that cutaneous necrosis is a preventable complication of levarterenol administration if careful observation for ischemic areas is carried out in all patients who have received levarterenol, with prompt institution of prophylactic instillation of phentolamine when indicated.*

Levarterenol (*l*-norepinephrine) (Levophed) bitartrate is a potent vasopressor agent. It is the specific active substance released at adrenergic nerve endings. The clinical indications for its use have included the hypotension associated with myocardial infarction, toxemia, sepsis, surgical removal of pheochromocytomas and sympathetic chains, and overdosage of adrenolytic agents. Its value in the treatment of hypotension associated with hypovolemia is questionable.

Cutaneous necrosis has been a serious complication of the intravenous use of levarterenol as evidenced by publication of reports of this complication in 61 patients during the period ending July, 1956.[1] The ultimate cause of the necrosis is prolonged ischemia of the skin and subcutaneous tissue due to marked constriction of the vessels supplying these tissues. The necrosis can readily develop when extravasation of levarterenol occurs. However, sloughs are common when extravasation is prevented by ligation of the vein containing a cannula. In this instance marked spasm of the vein and its vasa vasorum appears to be followed by diffusion of levarterenol into adjacent tissues. On the basis of experimental work in animals, three separate investigators[2] have recommended very similar methods for preventing this complication by local administration of phentolamine (Regitine) hydrochloride into ischemic tissues. This report is an analysis of the results of clinical use of one of these experimental methods during a three-year period at the Wood (Wis.) Veterans Administration Hospital.

Method

At the beginning of the study period all physicians and nurses in the hospital were apprised of the possibility of cutaneous slough occurring as a complication of administration of levarterenol. They were informed that according to laboratory experience, areas of ischemia are always present for at least four to six hours before irreversible skin changes occur and that these areas are obvious if one periodically examines the extremity for areas of pallor, decreased skin temperature, and tenderness along the course of the infusion vein.

Whether resulting from extravasation or diffusion, ischemic areas were infiltrated thoroughly subcutaneously with 5 to 10 ml. of saline solution containing 2.5 mg. of phentolamine and 300 units of hyaluronidase. For ischemic areas larger than approximately 30 sq. cm., one-half of the area was so infiltrated and the remaining half similarly infiltrated 30 minutes later. This practice was followed in order to avoid giving more than 2.5 mg. of phentolamine in one dose, although in no instance was there any detectable change in pulse or blood pressure after use of the phentolamine in the manner described.

After treatment of an ischemic area, the levarterenol administration was continued through the same vein unless, or until, an area of ischemia appeared for a second time. If this occurred the area was treated with the phentolamine mixture, and the levarterenol was subsequently administered through a cannula fed into an iliac vein through a high saphenous phlebotomy opening.

Physicians were requested to fill out a data sheet each time an area of ischemia was treated. This sheet requested information regarding the appearance of ischemic areas before and after treatment, an estimate of the duration of ischemia, and the eventual outcome of the treated area.

Results

Prior to the study period sloughs due to levarterenol occurred at the rate of from two to three per year at our hospital. Only one slough occurred in the three-year study period; this slough occurred in a patient whose extremity was not inspected periodically, and a large black gangrenous area of skin was present before prophylactic therapy could be instituted.

The phentolamine infiltration was used 26 times in 20 patients, and in no instance was there any observable systemic manifestation conceivably due to the phentolamine, and in no patient so treated did slough occur.

Clinical Investigator, Veterans Administration Center.

As indicated in the table, coldness and pallor were consistent signs of ischemia, the former being noted in 92% and the latter in 100% of the patients. Pain and edema were noted in approximately half the patients with significant pallor. Purple and white mottled discoloration was noted in five patients, and bleb formation was noted in these same five. Development of a slough appeared almost certain in these five patients prior to prophylaxis with phentolamine.

The average estimated duration of administration of levarterenol prior to the development of ischemia in these cases was 16 hours. In four cases ischemia appeared within two or three hours after administration of levarterenol was started. The duration of ischemia was roughly estimated when possible (utilizing observations made by patients and nurses, primarily) and averaged two and one-half hours, with a range of from one to five hours. Ischemia was not noted in any of the instances of administration of levarterenol directly into the iliac vein where a large flow is present.

Symptoms and Signs Noted in Patients with Impending Sloughs

	Patients	
	No.	%
Coldness	24	92
Pallor	26	100
Pain	15	58
Bleb formation	5	19
Mottled purple and white discoloration	5	19
Edema	13	50

Comment

Experimental evidence has indicated that phentolamine blocks levarterenol action on adrenergic effector cells. It is reasonable to assume that this is the mechanism by which phentolamine reverses the ischemia associated with extravasation or diffusion of levarterenol. It was effective in all instances in this series when given before development of obvious necrosis. Undoubtedly a contributing factor in the decreasing incidence of sloughs, however, is the increasing awareness of the problem on the part of physicians and nurses and the periodic inspection of extremities of patients to whom levarterenol is being administered. Tolazoline (Priscoline) hydrochloride has been successful in prevention of sloughs experimentally, but its relief of ischemia is slower and a much larger does appears to be necessary.[2a] Piperoxan hydrochloride has also been recommended after trial in four cases,[3] and on the basis of its pharmacological properties one could predict its clinical effectiveness. Both histamine and methacholine (Mecholyl) bromide iontophoresis have been used successfully,[4] but these would seem somewhat cumbersome methods in comparison with the other methods described.

Summary

The accumulated evidence indicates that cutaneous necrosis is a preventable complication of administration of levarterenol (*l*-norepinephrine) (Levophed) bitartrate. Careful observation of patients receiving the drug plus prompt institution of prophylactic infiltration with phentolamine has been completely successful in preventing sloughs during a three-year period.

PENICILLINASE FOR REACTIONS TO PENICILLIN.—Once a full-blown penicillin reaction occurs the drug of choice is penicillinase. This enzyme is not only dramatically life-saving in such an emergency but also it rapidly ameliorates the severe symptoms associated with the penicillin reaction. . . . One must remember that while the remarkable benefits of penicillinase are due to its capacity to completely inactivate penicillin as an allergen, it also destroys its therapeutic or antibiotic powers. Therefore, other antibotics or chemotherapeutic agents must obviously be employed if the clinical indications of infection still warrant such alternative therapy.—F. F. Yonkman, M. D., New Drugs for Old Uses and New Uses for Old Drugs, *The Journal of the Michigan State Medical Society,* June, 1959.

CLINICAL NOTES

CAROTID ARTERY THROMBOSIS IN PERSONS FIFTEEN YEARS OF AGE OR YOUNGER

Robert G. Fisher, M.D.
and
Karl R. Friedmann, M.D., Hanover, N. H.

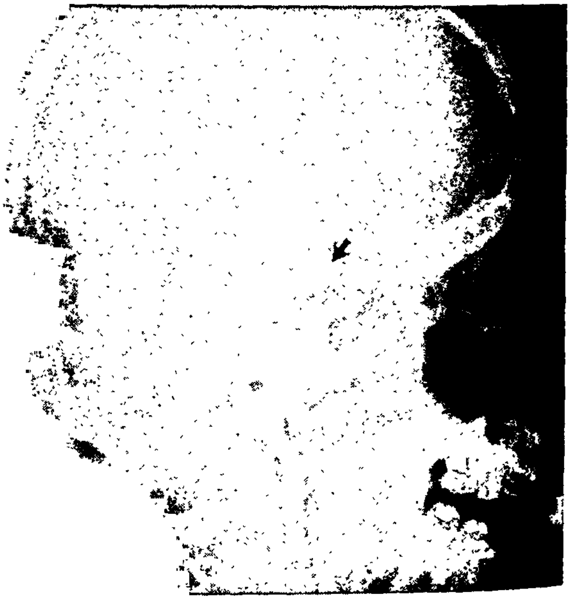
Thrombosis of the internal carotid artery is a major factor in the sudden occurrence of hemiplegia in patients 45 years of age or older. This entity may occur in persons 15 years of age or younger. Our experience with the following recent case has prompted a review of the literature.

Report of a Case

A 15-year-old high-school football player was admitted in a semiconscious condition with marked hemiparesis on the left. He had been in excellent health except for a mild headache prior to "warming up" on the football field. He suddenly fell to the ground unconscious and had a convulsion. He was taken to the office of a nearby physician and sent to the Mary Hitchcock Memorial Hospital. On examination he was drowsy, confused, and incontinent but not aphasic. There were no bruises about his scalp. His pulse was 60 beats per minute, but other vital signs were normal. A marked weakness of the face, arm, and leg was present on the left side, with an extensor plantar response. The abdominal reflexes were absent on the left. The carotid pulses in the neck were normal. On examination, the heart, lungs, and abdomen were normal. X-rays of the skull disclosed a questionable fracture in the right temporal region. Bur holes were made bilaterally to rule out an epidural hemorrhage; no abnormality was found. Bilateral carotid and vertebral arteriograms revealed a thrombosis of the right internal carotid artery just beyond the origin of the posterior communicating artery. Because of progression of the hemiparesis, anticoagulant therapy, as well as massage and passive exercises, was started. The patient was belligerent and disturbed throughout the first 10 days of his illness. The anticoagulant therapy was discontinued after two weeks, since his hemiparesis had not improved. However, a week later function began to return, so that 15 months after the onset of his illness he could walk with a spastic left leg. His left arm is useless. He has returned to school and is doing satisfactorily, although his work is reduced in both quality and quantity. There is no facial weakness.

Comment

We have found 16 cases reported in the literature of internal carotid artery thrombosis occurring in persons 15 years of age or younger. Since the majority of reports deal with the older age groups, one gains the impression that most cases are caused by arteriosclerotic changes in the vessel wall, which cause progressive narrowing of the lumen and thus predispose to thrombosis of the vessel. However, the factor of trauma has always been questioned in these cases—whether it be direct or indirect to the region of the neck. In the case we are reporting, one wonders if there may have been some injury to the carotid artery at the time the patient was "warming up" to play football.



Anteriogram showing thrombosis of right internal carotid artery.

From Mary Hitchcock Memorial Hospital.

In reviewing the cases of this study, no follow-up statements were available in 4 of the 16 cases. One patient died, and 11 were improved in their neurological status. Six of these 11 returned to normal. The sex was reported in 11 of the cases; it is of interest that 9 of these were males. No operations were performed on the artery. It is also of interest that one patient died after an initial episode at the age of 7 years.

Summary

A case of internal carotid artery thrombosis occurred in a 15-year-old boy. A survey of the literature indicates 16 other cases in children aged 15 years or younger. Of the 17 patients, only 6 are known to have returned to a normal neurological status.

Addendum

Since the submission of this report Stevens (*Pediatrics* 23:699, 1959) has published a report on three cases of carotid artery thrombosis, in girls aged 5½, 13, and 1. The first two cases are included in the table; only the one-year-old, who had endocardial fibroelastosis, has not been reported on previously. In this case the occlusion was at the siphon and the infant died two and one-half months after the onset of symptoms.

Summary of Reported Cases of Internal Carotid Artery Thrombosis in Persons Fifteen Years of Age or Younger

Author	Age, Yr.	Sex	History and Findings	Site of Occlusion	Treatment and Remarks
King, A. B., and Langworthy, O. R.: Arch. Neurol. & Psychiat. 46:835, 1941	7	M	Pneumonia 6 mo. before. Fell unconscious; awoke with hemiplegia on left. Blind right eye with white disk. Pupil larger. Spastic left-sided weakness	No angiogram	No specific treatment. Gradual improvement. Could walk unaided in 6 mo.
Krayenbuhl, H., and Weber, G.: Helvet. med. acta 11:289, 1944	15	F	Paralysis on left side at age 13. Recurrence 2 yr. later. Left-sided paralysis	1 cm. above origin	Vessel examined, but no follow-up available
Moniz, E.: Med. contemp. 65:111, 1947	14	M	Jacksonian attacks on right monthly since age 9. Weakness of right hand	At origin	Not stated
Riechert, T.: Nervenarzt 11:290, 1938	13	M	Headache. Paresthesias of right side of face. Ptosis and fixed pupil. Hemiparesis on left. Papilledema	At origin	Dilation of right anterior portion of lateral ventricle
Elvidge, A. R., and Werner, A.: A. M. A. Arch. Neurol. & Psychiat. 66:752, 1951	6	M	Spells of not being able to walk for 3 wk. Headache progressed to speech difficulty and right-sided weakness. Motor aphasia and homonymous hemianopsia on right. Hemiparesis and extensor plantar response on right	Narrowing internal carotid artery in intracranial portion. Poor filling of middle cerebral and no filling of anterior cerebral artery	No treatment stated. Dilation of ventricles on air study
Shapiro, R.: Radiology 58:94, 1952	5	M	Difficulty speaking and right-sided weakness. Onset after coma of ½ hr. Aphasia, homonymous hemianopsia on right, and flaccid paralysis and extensor plantar response on right	Region of siphon*	No treatment. Speech and right side normal in 6 mo.
Richter, H. R.: Acta radiol. 40:108, 1953	5	M	Aphasia and hemiplegia on right for 2 days	At origin	No treatment or follow-up stated
Cabieses, F., and Saldias, C.: Neurology 6:677, 1956	9	M	Weakness of right side for 2 days	At origin	Artery explored. Ethyl biscoumacetate and papaverine given. Normal in 6 mo.
Goldstein, S. L., and Burgess, J. P.: A. M. A. J. Dis. Child. 95:538, 1958	7	M	Sudden coma. Later, aphasia and hemiparesis on right. Day later more alert. Then right-sided seizures. Died after angiography	3.5 cm. above origin	Died 2 days after admission after deepening coma
Davidson, D. T., and others: Tr. Am. Neurol. A. 82:102, 1957	1 infant; 3 older children		Hemiplegia of sudden or gradual onset; inflammation of paranasal sinuses presumed cause in 1	1, at origin; 3, at siphon	3, clinical recovery; 2, persistent block on arteriogram
Stevens, H.: Ann. Int. Med. 49:1022, 1958	5½	F	Spontaneous carotid artery thrombosis		Recovered without residuals
	13	Not given	Acute episode		Hemiparesis on left after 5 yr.
Murphy, F., and Shillito, J., Jr.: J. Neurosurg. 16:24, 1959	10	M	Aphasia and hemiplegia on right	At siphon	Artery explored. Incomplete recovery in 12 days

ASSOCIATION OF MYXEDEMA HEART AND ARTERIOSCLEROTIC HEART DISEASE

Hermann Zondek, M.D., Jerusalem, Israel

When I first described the symptomatology of the myxedema heart 40 years ago[1] it was considered a rare variety of cardiac pathology. The myxedema heart is no longer a rarity. The increased rate of its reported incidence must be attributed to the great therapeutic advances made in the last decades in the field of thyroid disease, especially thyroid hyperfunction, such as antithyroid drugs and the clinical use of radioiodine.

The symptom complex of myxedema heart includes bradycardia, an often enormous dilation of the heart shadow, superficial heart contractions, a low cardiac output, flat or absent T waves with occasional lengthening of the Q-T interval in the electrocardiogram (ECG), soft heart sounds with correspondingly low waves in the phonocardiogram, and an abnormal venous pulse curve (absence of the auricular wave, a hump on the limb of the curve corresponding to ventricular systole, and complete absence of the normal diastolic fall). The latter two phenomena are only rarely referred to in the medical literature, although they are by no means less characteristic of the myxedema heart than the others.

The nature of the cardiac changes in myxedema is clearly demonstrated by the often dramatic effects of thyroid replacement therapy. In contradistinction to most other cardiac conditions, which at best only partially respond to adequate treatment, the various features of the myxedema heart regress promptly and fully as a result of thyroid medication. This response to therapy has been greatly accelerated by the recent introduction of thyroid substances such as sodium liothyronine and triiodothyroacetic acid which, having the same range of activity as the previously known ones, differ from them biologically only in the rapidity of their action. For example, in 1918 when I first studied the effects of thyroid substances on the myxedema heart, I found that 10 or 12 Gm. of desiccated thyroid given over a period of two months restored the size and function of the myxedema heart to normal. In 1928 I obtained the same results with 8 or 10 mg. of thyroxine, given over 20 days. In 1955 only 240 to 1,480 mcg. of sodium liothyronine, administered over 2 to 15 days, was required for the same purpose.

The reversibility of the cardiac alterations in myxedema argues against the long-held theory that the myxedema heart is a form of cardiac insufficiency rather than an essential, pathognomonic feature of the disease. Indeed, myxedema does not as a rule lead to cardiac insufficiency, even in untreated disease of long standing. It is true that, in an occasional patient, the myxedema heart and insufficiency of the heart muscle may coexist, but both must be regarded as distinct clinical entities requiring different therapeutic approaches. This is also true of the joint occurrence of the myxedema heart and coronary obliterating processes, e. g., arteriosclerosis (although myxedema, if untreated, may predispose toward arteriosclerosis). This combination is not always readily evident, as precordial pain may also occur in myxedema, and electrocardiographically the myxedematous alterations may mask the presence of other morbid phenomena which will be detected only after the former have cleared up as a result of specific therapy. A relevant case will be briefly reported.

Report of a Case

A 46-year-old woman complained of heaviness, obstinate constipation, and anginal pain, the latter being unresponsive to the usual therapy with coronary dilators.

Examination revealed, besides evidence of cardiovascular arteriosclerotic disease (blood pressure 170/90 mm. Hg, accentuation of the second aortic sound and a systolic murmur over the aorta, and dilatation of the aorta in which several sclerotic plaques were seen), the signs and symptoms of myxedema: typical outward appearance and behavior, dry skin, hoarse voice, slow speech, and sluggish Achilles-tendon reflexes. The basal metabolic rate was –23%; serum cholesterol level was 266 mg.%; the heart was dilated to both sides, though more to the left than to the right; and the electrocardiogram showed low voltage with flat or absent T waves. There was however no bradycardia (pulse rate between 72 and 86 per minute).

The patient received sodium liothyronine in daily doses of 120 mcg. for the first four days; thereafter the dosage was gradually reduced. As a result of substitution therapy a clinical remission, including a noticeable reduction in size of the heart shadow, was promptly achieved. One of the first signs was the disappearance of the myxedema pattern in the ECG after two days of therapy, i. e., after the administration of 240 mcg. of sodium liothyronine. In its stead a strain pattern became evident on the left side. It was concluded that this had been masked by the predominant myxedematous alterations, which are assumed to result from watery imbibition of the heart tissue. The precordial pain subsided after the administration of 660 mcg. of sodium liothyronine in seven days.

After regression of the myxedematous symptoms the patient's condition was satisfactorily controlled with administration of 0.1 Gm. of desiccated thyroid four times per week. As a rule only small maintenance doses are required and tolerated by patients with associated arteriosclerotic disease and myxedema. Larger doses are apt to provoke a recurrence of the precordial pain in such patients, although on different pathogenic grounds.

It is worthy of note that the pulse rate, blood pressure, and serum cholesterol level remained unchanged throughout the entire course of observation in this patient. This lack of response to specific therapy must be attributed to irreversible changes in the cardiovascular system and serum lipid levels brought about by the associated arteriosclerotic disease, as frequently observed in patients with untreated myxedema.

Summary

A 46-year-old woman complained mainly of anginal pain which was refractory to the administration of the commonly employed coronary dilators. Examination revealed, in addition to evidence of cardiovascular arteriosclerotic disease, the presence of myxedema including the characteristic electrocardiographic alterations of the myxedema heart. A prompt and full regression of the myxedematous symptoms was achieved with administration of sodium liothyronine. The myxedema pattern in the electrocardiogram disappeared after the patient had received 240 mcg. within two days, and a left strain pattern, previously masked by the myxedema, was found. The precordial pain subsided after seven days of substitution therapy. Subsequently the patient was kept in a euthyroid and clinically satisfactory state with administration of 0.4 Gm. of desiccated thyroid per week.

HUGE OSTEOMA OF THE ELEVENTH LEFT RIB

Israel Steinberg, M.D., New York

A huge osteoma of the 11th left rib had been present for over 50 years in a 71-year-old man. Operation had been recommended on many occasions but had been refused because the growth had caused the patient no discomfort. The roentgenographic appearance of the tumor suggested an osteoma which involved the rib and extended into the left pleural cavity above and retroperitoneally into the abdomen below. The histological nature of the tumor was confirmed when the patient died of hemorrhage due to cancer of the right kidney. This case is deemed worthy of report because of the unusually large size of the osteoma (3.5 lb.), its benign course, and the unusual appearance of the chest roentgenogram.

Report of a Case

A 71-year-old man was first admitted to the New York Hospital–Cornell Medical Center on Jan. 16, 1952, with the complaint of urinary retention. This symptom had first occurred 16 years prior to admission and had been completely relieved by transurethral prostatectomy performed at another hospital. He had remained well until onset of frequency, urgency, and nocturia two weeks prior to coming to this hospital. The patient recalled injuring the lower left part of his chest while doing calisthenics 51 years prior to admission; the next year a mass in the left flank was called to his attention. Since it had caused no symptoms, he had paid little attention to it. At another hospital, in 1936, he was urged to have the mass excised, but he had refused.

Physical examination showed a well-developed and well-nourished man in mild distress because of urinary retention. Rectal examination revealed an enlarged prostate. A large (15-by-15 cm.), stony hard, nontender, fixed mass was felt in the left flank beginning under the rib cage and almost reaching the iliac crest. There was increased anteroposterior diameter of the chest; the heart was not enlarged to percussion. A soft apical systolic murmur was heard; the blood pressure was 170/100 mm. Hg. The electrocardiogram was normal except for an increased QRS interval due to bundle-branch block. Bilateral inguinal hernia and varicose veins of the left leg were also found.

Roentgenographic examination of the chest showed slight enlargement of the left ventricle and elongation and tortuosity of the thoracic aorta

---

From the Department of Radiology, the New York Hospital–Cornell Medical Center.

(fig. 1, *left*). A huge, lobulated, calcified mass was seen in the left lower posterior lung field. A film of the lower left part of the thorax (fig. 1, *right*) showed the mass to measure 18 by 12 cm., and flaring and distortion of the left 11th rib was evident. The mass contained mottled, calcific deposits and extended retroperitoneally, displacing and distorting the left kidney (fig. 2).

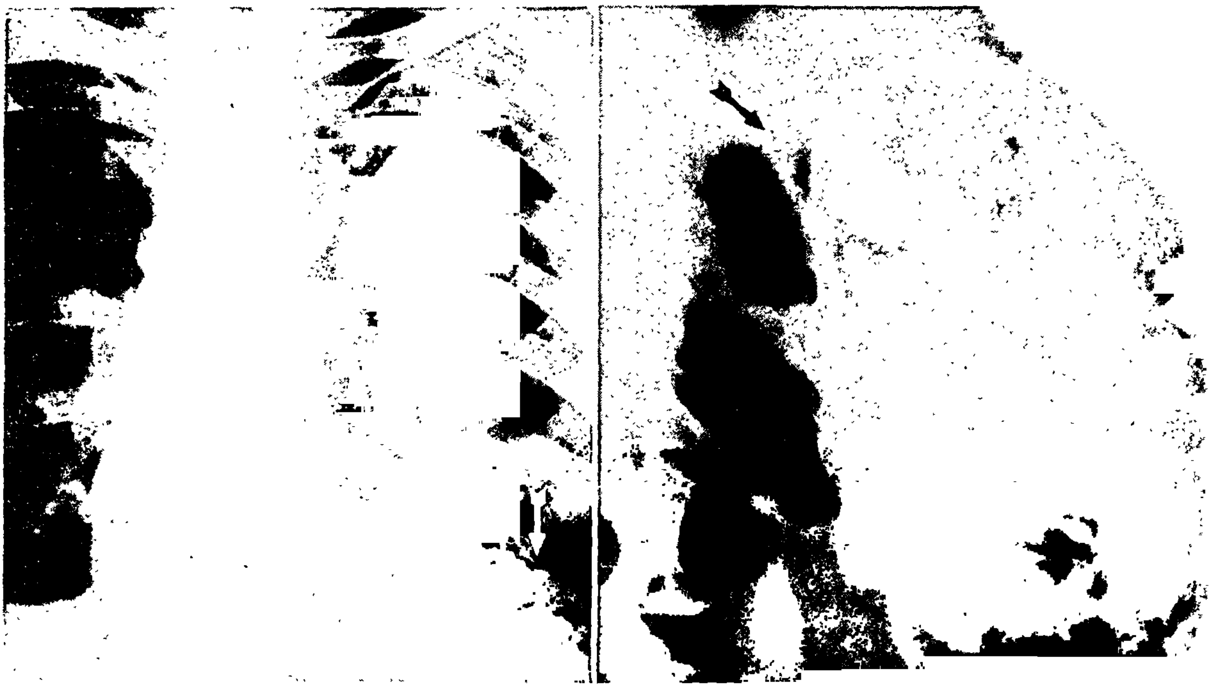

Fig. 1.—*Left*, frontal teleroentgenogram of chest showing calcific mass at left costophrenic angle (*arrow*). Heart is enlarged, ascending aorta is dilated, and aortic knob is prominent. *Right*, roentgenogram of lower thoracic cage showing huge lobulated (18 by 12 cm.) mass containing calcium; 11th left rib is flared and distorted (*arrow*).

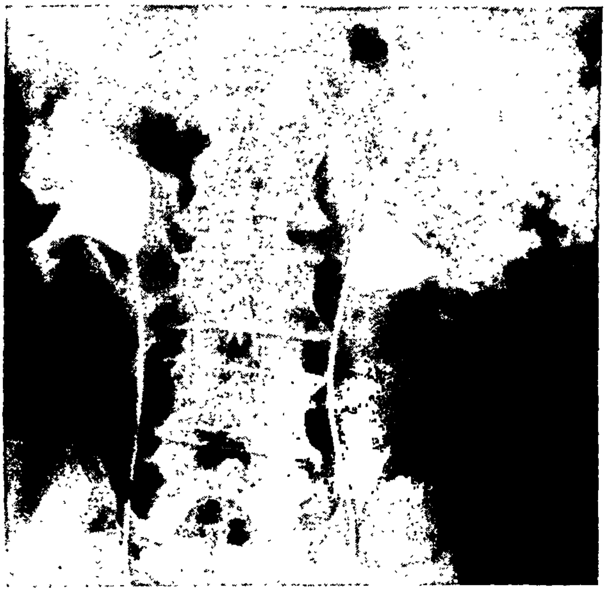

Fig. 2.—Retrograde pyelogram showing displacement of left kidney by calcified mass.

After the usual preliminary urologic studies, a transurethral prostatectomy was performed on Jan. 23, 1952. A left inguinal hernioplasty was also done on Feb. 1, 1952. On Feb. 8, 1952, the patient was discharged as improved.

Over four years later, Oct. 26, 1956, the patient was readmitted to the emergency service because of sudden onset of severe hematuria and colicky pain in the right inguinal region. Examination showed an acutely ill and dyspneic man. There were scattered rhonchi over the lungs. The hemoglobin level was 90% and the blood pressure 165/80 mm. Hg. A huge, stony, hard tumor in the right upper quadrant was again palpated. Ten ounces of blood-stained urine and clots was removed from the bladder. An hour later the patient became comatose and died suddenly.

Autopsy examination revealed extensive carcinoma of the right kidney, the greater part of which was destroyed by hemorrhage; a massive perirenal hematoma measured 20 by 15 by 6 cm. The left kidney was small and showed arteriosclerosis and arterionephrosclerosis. There was also arteriosclerotic heart disease with enlargement of the left ventricle which measured 2.2 cm. in thickness. General coronary arteriosclerosis was present with foci of fibrosis in the myocardium on microscopic examination. The lungs showed pulmonary edema, hyperemia, marked pulmonary emphysema, and bronchiectasis. Nodular hyperplasia of the prostate and chronic prostatitis were also found.

An ovoid, stony, hard mass in the left posterior pleural cavity measured 17 by 13 by 11 cm. and weighed 1,640 Gm. (3.6 lb.). It was attached to the 11th rib and had a bony shell; on the cut surface it appeared variegated and contained mixtures of bone, cartilage, and fat (fig. 3, *left*). Microscopically, pink, loose, fibrillar tissue was interspersed with bony spicules and foci of calcification and clumps of fat cells were seen (fig. 3, *right*).

Comment

In this era of modern surgery, tumors near the surface of the body are usually excised before they attain a large size. Although the mass described above was first noticed when the patient was 20 years of age, the usual time of discovery of osteomas,[1] he refused operation. At death, 50 years later, it had become huge but remained benign. Although the tumor distorted the rib at its origin, reached into the left pleural cavity and retroperitoneal space, and displaced the left kidney, it did not interfere with kidney function.

Osteomas arising from ribs are apparently not uncommon.[1] However, only one other example similar to the one herein reported could be found in the literature. Hodges and associates,[2] in their chapter on the roentgen diagnosis of diseases of bones, describe and illustrate an osteochondroma of the left 11th rib that occurred in a 19-year-old woman. Judging from the roentgenogram and photograph of the specimen, that tumor was smaller than the one described above. Also, the tumor in their case had been present only for four years prior to excision.

Summary and Conclusions

A 3.5-lb. osteoma had been attached to the 11th rib of a 71-year-old man for 50 years. Roentgenographic study of the tumor showed it to arise from the 11th left rib and contain calcium and bone; this readily established the diagnosis of osteoma. The tumor was located in the gutter of the left pleural space, causing findings on roentgenogram of the chest to stimulate a pulmonary mass. Despite the large size and displacement of the left kidney, the tumor remained benign; death was due to carcinoma of the opposite kidney.

525 E. 68th St. (21).

The Department of Pathology gave permission to report the pathological data in this study.

This study was aided by a grant from the Mallinckrodt Chemical Works, St. Louis.

EXCHANGE TRANSFUSION FOR ASPIRIN POISONING

Thomas L. Sterne, M.D., Victoria, Texas

This is a case report of a 6-week-old infant treated for aspirin intoxication by exchange transfusion. It is presented to call attention to the dangers of excessive aspirin administration and also to an emergency treatment. Despite a voluminous literature on the danger of salicylate intoxication, the average mother and many doctors still prescribe this drug as though it were harmless. Until such time as the entire medical profession and the general public become aware of the problem, we will continue to have unnecessary deaths caused by one of the most valuable drugs that we have available. The labeling of salicylates as potentially harmful is not sufficient to prevent overdosage, and the so-called safety caps on children's aspirin do not prevent accidental poisoning.

Report of a Case

A 6-week-old male infant was admitted to the DeTar Memorial Hospital on Dec. 24, 1958, at 11 p. m., with the history of an upper respiratory tract infection for two days, with progressive dyspnea. He had had a convulsion just prior to admission. His mother had given him a total of 12 grains (0.75 Gm.) of aspirin during the previous 48-hour period, but no other treatment had been given. Fluid intake had been poor.

On admission he had temperature of 103.5 F (39.8 C) rectally; his pulse rate was 180 per minute and respirations were 48 per minute. He appeared dehydrated and dyspneic. He was in opisthotonos and was cyanotic. A lumbar puncture was attempted, but no fluid was obtained. An x-ray on admission showed emphysema and one small area of increased density in the upper lobe of the right lung. His hemoglobin level was 9.5 Gm.%, with a hematocrit value of 24%; the leukocyte count was 20,100 per cubic millimeter, with a differential count of 65% segmented forms, 2% stab cells, and 33% lymphocytes. The carbon dioxide content was reported as 56 vol.%, chloride level 133 mEq. per liter, blood salicylate level 23 mg.%.

The patient was started on therapy with antibiotics, calcium gluconate, intravenously given fluids, and sedation for convulsions. He received a transfusion of 100 cc. of blood and vitamin K parenterally. During the night his convulsions were controlled and his respirations became less labored; he was improved the next morning but was voiding very little. At that time his carbon dioxide content was 44 vol.% and chloride level 103 mEq. per liter.

I first saw the infant at noon Dec. 25, 1958, because he was again having mild tonic seizures, was in constant purposeless motion, and was fretting, extremely dyspneic, and cyanotic, despite therapy with oxygen. At that time his blood pH was 7.9. He appeared well hydrated but was voiding only a few drops infrequently. His salicylate level at that time was 35 mg.%.

An exchange transfusion was done, using type-specific blood. His initial venous pressure was 30 cm. of blood at the umbilicus. A total of 310 cc. of blood was given and 420 cc. removed in 10-cc. portions. During the exchange his respiration rate slowed slightly, but the dyspnea was still marked. His general condition seemed slightly improved after the exchange. Venous pressure was still 30 cm. at the end of the exchange, despite a deficit of 110 cc. His salicylate level at the completion of the exchange was 29 mg.%. For these reasons a second exchange was done a short time later.

His venous pressure at the second exchange was 14 cm. at the beginning and 11 cm. at the end. A total of 475 cc. of blood was removed during the exchange and 500 cc. was replaced. His respiration and general condition improved during the second exchange, and at discontinuation of oxygen therapy he was without cyanosis. At that time his cry was very good and he slept quietly when left alone. His salicylate level was 23 mg.% after the second exchange.

By the next morning the infant looked very well, was voiding adequately, and was taking fluids by mouth. Blood examination showed the hemoglobin level to be 11.4 Gm., the hematocrit value 35%, and the white blood cell count 8,400 per cubic millimeter, with 68% lymphocytes and 32% segmented forms. He was discharged on the fourth hospital day and had no further difficulty.

Comment

Recently there have been many reports of salicylate poisoning, with much emphasis on methyl salicylate. In actual numbers of patients receiving an overdosage of any form of salicylates, aspirin poisonings outnumber many times those of any other salicylate. Infants and small children are especially prone to develop symptoms from accidental overdosage or iatrogenic causes. They are easily dehydrated by the primary illness, which prompts the administration of the aspirin, and are often oliguric. Approximately 20% of ingested salicylate is destroyed in the tissues; the remainder is excreted by the kidneys. If there is inadequate urinary output, there is, of course, inadequate elimination of the drug. If inadequate elimination is combined with overdosage, symptoms may appear rapidly, especially in young infants whose renal function is not fully developed.

Cann and Verhulst [1] have given an excellent discussion of salicylate poisoning that thoroughly covers the subject. They review the pharmacology, pathophysiology, and presently accepted method of treatment in a very readable, concise, and accurate manner.

No explanation can be given for the presence of alkalosis approximately 24 hours after the last dose of aspirin in the patient reported here, since usually acidosis replaces alkalosis within six to eight hours. This and his failure to respond to more conservative measures probably were the results of his oliguria. It was felt that the exchange transfusion in this case not only removed salicylate from the body but also corrected the electrolyte imbalance.

The mainstay in the treatment of salicylate poisoning consists of giving fluids intravenously to correct the existing water deficit and maintain adequate urinary output. Other details of therapy are fully covered by Cann and Verhulst.[1]

If more conservative measures fail, hemodialysis should be seriously considered. Even though the number of institutions offering this procedure is increasing, there are many areas where it is not readily available. An exchange transfusion readily accomplishes the same result and can be performed in any hospital where fresh blood is available. This is particularly adaptable to infants and young children because of the small circulating blood volume.

Summary and Conclusions

A young infant had acute salicylate intoxication which failed to respond to fluid and electrolyte therapy. He was treated by two successive exchange transfusions. Recovery followed without incident. This method of therapy is proposed under these circumstances in young infants when hemodialysis cannot readily be done.

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following report.

H. D. Kautz, M.D., *Secretary.*

This report was prepared by the Subcommittee on Blood Dyscrasias to bring to the attention of the medical profession the existence of the Registry on Blood Dyscrasias.

Norman De Nosaquo, M.D., *Secretary,*
Committee on Research.

DEVELOPMENT AND PURPOSE OF THE REGISTRY ON BLOOD DYSCRASIAS

An increasing number of drugs and other potentially toxic compounds found in industries, in the home, and in our daily contact are being introduced every year. Untoward reactions to some of these substances may be so rare as to avoid detection, even after careful field test prior to release to the public. Although these reactions may be rare, they can be very serious on occasion. This is particularly true of the drug-induced blood dyscrasias. It is impossible to differentiate clinically between a case of drug-induced marrow depression and one which apparently occurs spontaneously.

An investigator working independently might have difficulty assessing accurately the occasional hematological ill-effect he may see from the use of a drug. However, the collective experience of a number of observers may be helpful. For this reason, the Registry on Blood Dyscrasias of the Committee on Research of the American Medical Association was established to assemble reports of blood dyscrasias in which drugs and toxic agents conceivably played a role. The registry is intended as a means of alerting the medical profession to such possibilities. It is not meant to be a repository for authoritative or statistical information.

The Subcommittee on Blood Dyscrasias conducted a two-year pilot study and has reviewed the accumulated data. It has concluded that this information could serve as an early warning system for the medical profession. The summaries, which are prepared semiannually, will be distributed widely, in the hope that physicians will become aware of the existence of the registry and will report cases. The current summary has been distributed to the following groups: state and county medical societies, hospitals, medical school libraries, and departments of pharmacology, pathology, medicine, and pediatrics of all medical schools. Physicians may examine this information at these sources, or they may write to the Committee on Research, American Medical Association, for copies. In the summary for the second half of 1958, 427 cases have been reported to the registry by physicians in the United States and Canada since 1953, and some cases have been taken from the literature. Reports are accepted by the registry only when the drug or toxic agent was administered to the patient within six months prior to the appearance of the dyscrasia. It is evident that inclusion of a drug in the list does not necessarily mean that it is harmful or that it was the cause of the reported dyscrasia. The information contained in the summary is not to be considered authoritative or statistically significant, since these data are "raw" and undoubtedly represent only a small segment of the total number of cases which probably occur.

When a patient develops a blood dyscrasia after use of a single drug, there is stronger circumstantial evidence of an etiological relationship than in instances in which many drugs were administered. If it is well known that one of the drugs administered may cause the dyscrasia, suspicion should not rest as heavily on the other drugs, especially if they are not known to cause a dyscrasia.

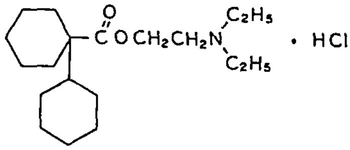
The continued effective operation of the registry depends on the cooperation of physicians who have seen patients with blood dyscrasias which they suspect might have been induced by a drug or toxic agent. The form used in reporting cases to the registry may be obtained by writing to the Secretary, Committee on Research, American Medical Association, 535 N. Dearborn St., Chicago 10.

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based upon available evidence and do not in any case imply endorsement by the Council.

H. D. KAUTZ, M.D., *Secretary.*

Dicyclomine Hydrochloride (Bentyl Hydrochloride).—2-Diethylaminoethyl bicyclohexyl-1-carboxylate hydrochloride.—The structural formula of dicyclomine hydrochloride may be represented as follows:



Actions and Uses.—Dicyclomine hydrochloride is a synthetic anticholinergic drug which is used clinically for its atropine-like effects on the gastrointestinal tract. It acts both on neuroreceptor sites innervated by postganglionic parasympathetic fibers and directly on smooth muscle tissue; there is no evidence for ganglionic blockade. After oral or parenteral administration to animals, dicyclomine causes a delay in gastric emptying, inhibits the propulsive motility of the small intestine, partially relieves morphine-induced spasm of the sphincter of Oddi, strongly antagonizes the intestinal effects of acetylcholine and related cholinergic compounds, and exerts a mild inhibiting effect on the tonus of the isolated dog ureter. In these respects, the drug is less potent than atropine. It is much less potent (1/300 to 1/400) than atropine in mydriatic or antisialogogue action and is virtually free of the cardiac effects of the belladonna alkaloids. Dicyclomine exerts little, if any, gastric antisecretory effects.

Dicyclomine hydrochloride is used for the symptomatic management of functional disorders of the gastrointestinal tract which are characterized by hypermotility and spasm and which may occur as a primary disturbance. Since the drug exerts a spasmolytic effect on the lower as well as the upper portions of the intestine, it may be used in functional intestinal distress (irritable colon, spastic constipation, mucous colitis, spastic colitis). It is also proposed for use in pylorospasm and biliary dyskinesia, but, in view of the questionable clinical status of these functional diagnoses, the usefulness of anticholinergic therapy in such cases is uncertain. There is little convincing evidence that antispasmodics such as dicyclomine are of value in the management of cardiospasm.

The drug may also be used as an adjunct in the therapy of certain organic diseases of the gastrointestinal tract. These include peptic ulcer, ulcerative colitis, and diverticulitis. Since dicyclomine does not inhibit gastric secretion, concomitant administration of antacids is imperative when the drug is used in the treatment of duodenal ulcer. The value of anticholinergic drugs, including dicyclomine, for the treatment of esophagitis, gastritis, duodenitis, and cholecystitis is considered dubious. Likewise, there is little rationale for the employment of such agents in patients with asymptomatic diverticulosis or hiatal hernia; complications arising from such conditions are predominantly surgical, rather than medical, problems.

Dicyclomine is virtually free of some of the more troublesome atropine-like side-effects, thus permitting more general use of the drug in conditions in which secretory inhibition is not of the first import. In the doses used clinically, mydriasis or cycloplegia has not been a problem. The drug can safely be used in patients known to have glaucoma. It likewise causes little xerostomia. Urinary retention in patients with prostatic hypertrophy has not been encountered. In occasional instances, patients may complain of slight dizziness and a feeling of abdominal fulness or experience brief periods of euphoria. It is contraindicated in patients with frank urinary retention, stenosing peptic ulcer, and pyloric or duodenal obstruction.

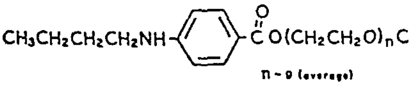
Dosage.—Dicyclomine hydrochloride is administered orally or intramuscularly. By either route, the usual dose is 20 mg. for adults, 10 mg. for children, and 5 mg. for infants. The frequency of administration varies from three to four times a day. Some adult patients with severe gastrointestinal spasticity or hypermotility may require doses of 25 to 37.5 mg. three times daily for adequate relief of symptoms.

Preparations.—capsules 10 mg.; solution (injection) 20 mg. in 2 cc., 100 mg. in 10 cc.; syrup 2 mg. per cc.

Year of introduction: 1950.

The Wm. S. Merrell Company cooperated by furnishing scientific data to aid in the evaluation of dicyclomine hydrochloride.

Benzonatate (Tessalon).—ω-Methoxypoly(ethyleneoxy)ethyl *p*-butylaminobenzoate.—The structural formula of benzonatate may be represented as follows:



Benzonatate is a pale yellow, viscous liquid.

Actions and Uses.—Benzonatate was introduced in 1956 as an antitussive agent. It is chemically related to the local anesthetic, tetracaine, by replacement of the dimethylamine group with a methylated polyethylene glycol, and is one of a number of derivatives of local anesthetics screened for relatively high specificity toward sensory receptors of vagal afferent fibers involved in the production of cough. It is postulated that, after systemic absorption, benzonatate produces an inhibitory effect on these peripheral structures similar to that which would result from topical application of a local anesthetic to the respiratory mucosa. However, benzonatate also acts upon the central nervous system, since it inhibits transmission of impulses of the cough reflex in the vagal nuclei of the medulla and strongly depresses polysynaptic spinal reflexes. The relative importance of the peripheral and central activity of benzonatate in producing its antitussive effects in man remains to be determined.

Benzonatate has been reported to inhibit cough experimentally induced in animals by insufflation of soap powder and in man by inhalation of aerosols of citric acid solutions, with approximately the same efficiency as codeine. Unfortunately, benzonatate seems relatively less effective against the cough associated with clinical illness than against that induced artificially, when it is compared with codeine.

On the basis of early clinical trials, it may tentatively be concluded that benzonatate is effective in some patients in suppressing, to a varying degree, cough due to acute or chronic bronchitis and tracheitis, pulmonary tuberculosis, bronchiectasis, advanced emphysema, early bronchogenic carcinoma, and bronchial asthma. It appears to be ineffective in preventing the cough associated with bronchoscopy and other manipulative procedures. Reports concerning the effects of benzonatate on the volume and character of respiratory secretions are conflicting; there is no definite proof that it is an expectorant.

In contrast to codeine and other opiate antitussives, benzonatate does not depress respiration. On the contrary, in bronchial asthma, it is reported to increase rate and depth of respiration and respiratory minute volume; vital capacity is also augmented. Subjective relief of dyspnea is often reported, despite this respiratory stimulation and despite the fact that rate of expiratory flow is not altered. Similarly, in pulmonary fibrosis and emphysema, improvement is seen in exercise tolerance, accompanied by an increase in tidal volume, but without any change in expiratory velocity. Here, however, no significant alteration of vital capacity occurs.

When given by mouth, benzonatate produces no detectable effect on the cardiovascular system. Even after intravenous injection, benzonatate has little effect, although a small, transitory rise in blood pressure sometimes occurs.

When given orally, effects may occur within 10 to 20 minutes and last two to eight hours.

Benzonatate is well tolerated in therapeutic doses. No reports of serious toxicity have yet appeared. The total incidence of side-effects is low. Among those reported are drowsiness, nausea, skin eruption, nasal congestion, dizziness, and a sensation of burning of the eyes and of numbness or tightness in the chest. If the capsules are allowed to dissolve in the mouth, they exert a local anesthetic effect on the mucosa that is disagreeable to a few patients. Side-effects characteristic of those caused by codeine and other narcotic antitussives are largely absent. Habituation, euphoria, respiratory depression, or constipation have not been reported.

Benzonatate may be used for the symptomatic relief of cough. It must be remembered, however, that suppression of a productive cough may be harmful in some cases and that such suppression is usually inadvisable in the immediate postoperative period. In such instances, the use of benzonatate or other antitussive agents is contraindicated. For the present, the use of benzonatate for the relief of dyspnea must be regarded as experimental.

If further clinical investigations confirm early reports, benzonatate may be regarded as a valuable addition to the available antitussives and one which is notably free from serious toxicity. Regrettably, much of the information now available is drawn from isolated case reports and clinical experiments of which the experimental designs are subject to criticism. Since there have been only a few controlled investigations comparing benzonatate with other antitussive agents, no definite statement can be made regarding its efficacy relative to other drugs of this type.

Dosage.—Benzonatate is given orally. The suggested dosage is 100 mg. given three to six times daily. The capsules should not be chewed.

Preparations: capsules 50 mg. and 100 mg.

Ciba Pharmaceutical Products, Inc., cooperated by furnishing scientific data to aid in the evaluation of benzonatate.

COUNCIL ON FOODS AND NUTRITION

PROGRAM OF THE COLUMBIA UNIVERSITY INSTITUTE OF NUTRITION SCIENCES

W. Henry Sebrell Jr., M.D., New York

Physicians and members of the allied professions specially trained in the field of public health are needed badly. Many universities offer a curriculum and encouragement to the student both from the United States and from foreign lands in the field of public health. Tulane University Medical School, the University of Pittsburgh, Harvard University School of Public Health, and Vanderbilt University School of Medicine, for example, can accommodate the student who finds an interest in the field of international nutrition. The Institute for Nutrition Sciences at Columbia University has been developed especially to meet this need. When, in the preliminary stages of development of this institute, it became obvious that a person must be chosen as director who had the unique qualities of devotion to public health, a wide experience in the field of nutrition, and the foresight for devising a program that could be followed through many years, Dr. W. Henry Sebrell Jr. was selected as that director. The Council on Foods and Nutrition is pleased to call attention to this new school at Columbia and will encourage its further development. The Council has authorized publication of the following report about this program.

PHILIP L. WHITE, SC.D., *Secretary.*

Malnutrition adversely affects the life, development, and health of more people in the world than any disease. It kills millions of infants and small children and stunts the development of millions of other children, especially in the technically underdeveloped areas. Metabolic diseases, which can be controlled to some extent by nutritional management, are also of major concern in the nondeveloped countries. Yet, there are only a few physicians and public health workers who have been trained to deal effectively with the problem. This world shortage of people adequately trained in the public health aspects of nutrition is a serious handicap to progress in improving nutrition in all countries. Such people are needed both by the United Nations organizations and by national governments and departments of health.

Recognizing this need and seeing the great opportunity to meet the situation, Dr. C. Glen King, through the resources of Columbia University, planned and organized the Institute of Nutrition Sciences. Dr. King, who is a member of the faculty of Columbia University and director of the Nutrition Foundation, Inc., served as the institute's acting director until last year. Dr. King will continue his close personal interest as a member of the faculty committee and the advisory board. The first students were accepted in September, 1958.

The Institute of Nutrition Sciences, although primarily a graduate teaching institute, will conduct a broad research program as an essential part of adequate graduate instruction and to fulfill the need for additional knowledge about human nutrition. Since the program of the institute is oriented toward public health, it is placed administratively in the School of Public Health and Administrative Medicine, but students may take courses as needed in any part of the university or its affiliated organizations.

The program of study is organized to teach the student the underlying causes of malnutrition, the extent and distribution of the various kinds of

---

Director of the Institute of Nutrition Sciences, Columbia University.

malnutrition, the procedures for conducting an assessment of human nutrition, and the diagnosis, treatment, and prevention of malnutrition. A graduate of the institute will be competent to plan and carry out comprehensive public health nutrition programs of national scope and will be able to understand the complex international problems in the production and movement of foods. Insofar as we know, such a course is not now available anywhere else in the world. The instruction includes courses on food production and agricultural economics, food technology, food laws and regulations, biochemistry and food chemistry, human nutritional requirements, biostatistics, health education, epidemiology, the assessment of nutritional status, deficiency diseases and their control, the social aspects of nutrition, and the management of national and international public health nutrition programs.

A course of study will be selected to meet the needs of the individual student on the basis of his past training and experience, as well as the work he plans to do and the country in which he plans to work. The degrees being offered are an M.S. in nutrition and a Ph.D. in nutrition. A special course for physicians is being developed which will enable the student to obtain an M.P.H. and an M.S. in nutrition within 18 months. The M.S. degree is intended primarily for those students who anticipate working on the public health problems of nutrition, especially in technically underdeveloped areas. The Ph.D. is, of course, intended for the advanced student of exceptional ability who can meet the requirements in the basic sciences and modern languages in addition to carrying out an original investigation leading to a satisfactory thesis.

However, the program differs from most academic programs in nutrition in that three months of field work in nutrition is a requirement for any of the degrees. This field work also will be planned on an individual basis and will vary widely in location and type, ranging from work in a state or a large city health department to a national health department or a village in a technically underdeveloped area. In order to carry out such a program adequately, the institute has already initiated plans for cooperative training and study with research and educational institutions and health organizations in several parts of the world. It is anticipated that many of the students will be from foreign countries and will want to learn to deal with malnutrition as it exists in their own country. Since these problems and their solutions are so widely varied, several training centers will be necessary in different parts of the world. It is therefore anticipated that the program of the institute will be international in its scope, although centered in Columbia University.

The research program is planned as an adjunct to the teaching program and will be conducted in three main categories. The first of these will be field studies dealing with nutrition surveys, the assessment of nutritional status, problems in controlling malnutrition, and similar work. This area is under the direct supervision of Dr. Elmer L. Severinghaus, professor of public health nutrition. An extensive survey was carried out in Haiti during the past summer, and the data are now being prepared for publication. A cooperative project is under way in Puerto Rico, and others are being planned.

The second main research area is in that of human metabolic diseases and their relation to nutrition. This area of research is under way in St. Luke's Hospital in New York City in collaboration with and under the direction of Dr. Theodore B. Van Itallie, medical director and assistant in medicine and with Dr. W. Henry Sebrell Jr., director of the institute and a consultant in nutrition at St. Luke's Hospital. This program involves controlled metabolic studies on patients with various diseases such as atherosclerosis, arteriosclerotic heart disease, and diabetes. A metabolic unit and beds for special studies, with the necessary supporting biochemical laboratories and research animal facilities, are available.

The third main area of research is that of fundamental biochemical work in nutrition. Since new laboratory facilities are required, this is now in the planning stage. The architect's drawings have been completed, and it is anticipated that the program will be under way in less than a year.

Since the institute represents a new educational venture of potentially great international significance, an advisory board has been created which consists of distinguished and well-qualified citizens with broad international interest. This advisory board is under the honorary chairmanship of the Honorable Herbert Hoover. The active chairman is Mr. Clarence Francis, consultant to President Eisenhower on agricultural and food problems. Other members of the board are:

Joseph W. Barker
Ernest T. Baughman
Leona Baumgartner
Frank Boudreau
William T. Brady
Leroy E. Burney
George H. Coppers
T. L. Daniels
Thomas C. Desmond
Edward H. Green
Herman E. Hilleboe
Holgar J. Johnson
C. Glen King
The Rev. Msgr. Luigi Ligutti
Mrs. Oswald B. Lord
Berwyn F. Mattison
Samuel R. Milbank
Fairfield Osborn
Maurice Pate
George W. Perkins
Albert C. Simonds Jr.
Benjamin Strong
C. Cullen Thomas

The institute, with such able guidance, should make a significant contribution to preventive medicine throughout the world.

POSTGRADUATE CONTINUATION MEDICAL EDUCATION

IN ITS efforts to be of assistance to members of the medical profession in their continuing education, the Council on Medical Education and Hospitals presents its annual list, Postgraduate Courses for Physicians, in this issue of THE JOURNAL for the year beginning September 1, 1959. Unlike the lists of medical schools, internships, and residencies published in THE JOURNAL, the information on postgraduate courses does not carry either approval or disapproval by the Council of the programs listed, and such should not be inferred by the reader.

The *ad hoc* Advisory Committee on Postgraduate Medical Education has recommended to the Council that a mechanism should be developed and implemented for the appraisal of the postgraduate educational resources of institutions and organizations active in this field. The Committee and the Council staff have been developing and pilot-testing such a mechanism during the past two years. A large-scale test is now in progress. If the appraisal mechanism under study is proved to be a valid and feasible approach for the preparation of a selective listing, then such data and recommendation will be considered by the Council. Such a selective list of postgraduate courses, if authorized, would provide a central reference of those educational programs sponsored by institutions and organizations having adequate postgraduate educational resources in terms of the basic principles[1] published two years ago.

It is the consensus that worthwhile educational programs more effectively utilize the physician's time and are likely to whet his appetite for participation in other educational programs. Conversely, those programs lacking sufficient advance planning or utilizing pedestrian approaches that are relatively less effective educationally often discourage the participating doctor from continuing his education in other courses.

The recently published geographically oriented study of postgraduate courses and enrollments[2] demonstrated that doctors of medicine travel relatively great distances to postgraduate courses, and especially to those located in medical schools and their teaching hospitals. The facilities and personnel at medical schools and other medical centers are to an increasing extent utilized in an educationally meaningful manner in postgraduate courses, including an annually increasing number of individually arranged postgraduate traineeships in various fields. It seems reasonable to believe that there is a large potential demand on the part of the medical profession for a greater number of better postgraduate courses to help them remain abreast of the deluge of new knowledge. The Council hopes that the appraisal mechanism now under study will make it possible for future listings to indicate that the courses included are all likely to be worth the expenditure of time, intellectual energy, and money by the medical profession.

A major objective of the Council in its long-range planning relative to the continuing education of the medical profession has been and is to secure information that will be useful to all concerned as well as to identify and stimulate constructive action. That publication of an annual listing has been widely accepted is indicated by the fact that information on nearly all of the courses eventually coming to the attention of the Council office is submitted sufficiently in advance for inclusion in the list. This represents a constantly greater and more desirable degree of advance planning.

An innovation this year to make the list more useful is inclusion of a geographical cross-reference list in order that courses offered in each city may be more readily found in the listing.

THE AUTOCLAVE AND CROSS-INFECTION IN HOSPITALS

The problem of who is responsible for sterilization of supplies and equipment in hospitals has been studied by the Working Party of the Medical Research Council of London, England.[1] Their report is based on extensive and detailed investigations into existing arrangements for sterilization of surgical equipment in hospital wards, surgical units, sterile-supply departments, laboratories, and pharmacies in England.

Other recent publications[2] point out the importance of good housekeeping in hospitals—the need of more intensive application of the standard concept in aseptic and antiseptic methods in order to control the incidence of staphylococcus infection.

The possibility that cross-infection can take place in autoclaves is recognized. The Working Party in England concluded that, while there were a number of underlying factors for faulty sterilizing procedures by heat, two important factors usually stood out, namely: 1. There was a lack of understanding of the technical requirements involved in sterilizing by autoclaves. 2. No one member of the medical staff was given the final responsibility for overseeing the sterilizing procedure. The battle of asepsis can be won only by continual diligent application of the correct technique and by perpetual awareness and persistent observation by the physician in charge of sterilizing procedure. According to the directions for the correct operation of the autoclave, to kill the most resistant bacteria and their spores the air should be removed from the interior of the autoclave and the contents exposed to saturated steam at a pressure of 20 lb. per square inch (1.4 kg. per square centimeter) (126 C) for as long as 30 minutes. The Working Party found the use of a vacuum to remove the air less effective (unless used correctly) than the downward-displacement, that is, making sure the air is displaced by steam in the sterilizers. The personnel in charge of operating the autoclave should be trained and made aware of the problems and technique. The essential criticism in most instances has been divided responsibility, and the remedy clearly is to put one competent person in charge.

NEW REGISTRY ON BLOOD DYSCRASIAS

A report in this issue of The Journal (page 1925) outlines the purpose of a registry sponsored by the Subcommittee on Blood Dyscrasias of the Committee on Research of the Council on Drugs. The Registry on Blood Dyscrasias has been set up for the express purpose of alerting the medical profession to the possible toxic effect on blood and bone marrow of drugs or chemical agents. It is not intended to provide statistical information on the incidence of such conditions but to assist physicians in recognizing such possibilities. There may be doubt in some cases as to whether there is a causal relationship between the condition and the use of the substance. The accumulation of a larger number of cases will make it possible to determine with greater certainty whether a causal relationship exists. The untoward side-effect of many of the newer therapeutic agents may not become apparent until the drug has had wide distribution. It is hoped that the registry can serve a useful purpose by alerting physicians and that they, in turn, will report all cases in which they suspect such a possibility. The success of the project will depend therefore on the cooperation of the physicians of the United States. Copies of the summary tabulation and report forms may be had by writing to the Secretary, Committee on Research, American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois.

CHANGE OF ADDRESS

If you change your address please notify The Journal at least six weeks before the change is made. Include the address label clipped from your latest copy of The Journal, being sure to clearly state both your old and new address. If your city has Postal Zone Numbers, be sure to include this Zone Number in your new address.

ORGANIZATION SECTION

STATEMENT OF DR. LEONARD LARSON ON H. R. 4700, BEFORE WAYS AND MEANS COMMITTEE OF HOUSE OF REPRESENTATIVES

Mr. Chairman and Members of the Committee:

I am Dr. Leonard Larson of Bismarck, North Dakota. I am appearing here today as the Chairman of the Board of Trustees of the American Medical Association. With me is Dr. Frederick C. Swartz of Lansing, Michigan, who is Chairman of the American Medical Association's Committee on Aging.

Dr. Swartz will present the basic reasons for the position of the medical profession concerning H. R. 4700, 86th Congress. Initially, however, I would like to report briefly to the Committee concerning the sustained progress that is being made under the present system of health care in this country.

Slightly more than one year ago, I appeared before this Committee and pledged the American Medical Association to a dedicated, continuing effort in the field of health care for the aged.

I am proud to be able to tell you that the American Medical Association is making good on that pledge.

I say this with humility, because the very real progress being made represents the cooperative effort of hundreds of thousands of our citizens—doctors, nurses, dentists, social workers, hospital staff members, insurance company personnel, community and religious leaders—all working voluntarily together to do the job.

It is also to the credit of these private citizens that they are proving their ability to do the job in their own communities—and to do it effectively and well. A few specifics from their record of accomplishment are appended to our testimony.

At this time it is enough to say that retirement villages, new nursing homes, chronic disease care centers, home care programs, recreational facilities and research projects have been established and that many, many more are on the way.

The medical profession takes pride in the part it has played thus far, and accepts its continuing role of leadership and support in the years ahead with confidence. We believe that the ultimate solution to the problems that remain must be found in private and voluntary action at the community level, and in private health insurance.

Let me say a few words on the subject of voluntary health protection insurance, which has made revolutionary progress since World War II. Yet as rapidly as it has expanded in that period it seems to be gaining momentum still.

At the end of 1945, only 32 million people were covered by voluntary health insurance. But by the end of 1958, the number had soared to 123 million.

Putting it another way, fewer than one American out of three in 1945 had voluntary health insurance. Yet today, the figure is nearly three out of four.

This is important, because it indicates that prepayment plans and the health insurance industry, by providing more and expanded health coverage for all age groups, are anticipating and solving tomorrow's health care financing problem of the aged.

H. R. 4700 fails to take into account the ever-increasing number of persons who will be covered by private health policies when they reach age 65, and the increasing public awareness of the value of voluntary health insurance protection.

Last December, the A. M. A. House of Delegates, aware of medicine's responsibility in this regard, adopted a proposal which applies specifically to those over 65 with modest resources or low family income. This proposal urged physicians to set their fees at a level which will encourage the continued development of insurance and prepayment plans at reduced premiums.

Our state and local medical associations have been moving promptly to make this policy effective.

I am happy to report that there are now 25 plans in 23 states offering Blue Shield programs for those over 65. Further, in sixteen other states, our medical societies, in cooperation with the plans they sponsor, are working out plans of a similar nature.

The progress of Blue Cross and Blue Shield is only part of the story. An ever-increasing number of private insurance companies are now making initial coverage available to those over 65 on an individual basis and, at the same time, improving the type of health insurance coverage provided.

According to the Health Insurance Association of America, 60 per cent of our senior citizens who need and want health insurance will have protection by the end of next year. Further, that percentage will increase until three-quarters will be covered in 1965, and 90 per cent in 1970.

Private insurance and prepayment plans are rapidly doing the job.

But their gains would be nullified by passage of H. R. 4700, which would undermine and gradually replace voluntary health insurance if it were allowed to become law. Few people would be willing or able to carry both government and private plans.

In addition to discussing the progress which has been made in developing financing mechanisms, it should also be remembered that the medical profession has, for many years, intimately concerned itself with the health care of the aged. I believe that the record of medical accomplishment attests to the fact that we have translated this concern into positive action. It should be understood in this connection that medical progress is linked irrevocably with the opportunity of medical researchers and practitioners to work with complete freedom.

Since the beginning of the Twentieth Century, medicine has made revolutionary advances that have lengthened life and opened entirely new approaches to curing illnesses. Since 1900, better medical care has increased the life expectancy of the average American by 20.5 years.

This means that the medical profession itself has helped to swell the ranks of our aged population. We are proud of this, and are convinced that we can meet future challenges in the same way, with the same success and with the same benefits to mankind.

We believe, therefore, that any proposal that would undermine or destroy the voluntary progress we are now making should be defeated. We believe a federal compulsory health care system can lead only to disillusionment and to inferior medical care for those millions of older citizens who deserve the opportunity of making their extra years rewarding.

With your permission, Mr. Chairman, I would like to call on Dr. Swartz to present additional views with respect to H. R. 4700.

We will then be happy to answer any questions that members of the Committee may have.

STATEMENT OF DR. FREDERICK C. SWARTZ ON H. R. 4700, BEFORE WAYS AND MEANS COMMITTEE OF HOUSE OF REPRESENTATIVES

Mr. Chairman and Members of the Committee:

As Dr. Larson has told you, the medical profession is opposed to H. R. 4700, 86th Congress, now pending before this Committee. Before presenting my statement, I should like to thank the Committee on behalf of the American Medical Association for the opportunity to testify.

The fundamental and over-riding reason for the opposition of medicine to this legislation is that it would, in our opinion, result in poorer—not better—health care for the people of this country. The American Medical Association's objective is—and always has been—to work toward the better health of Americans of all ages.

We are for all proper courses of action which will help us attain that objective. We are against any course of action which hinders or prevents its attainment.

As a doctor, it is my daily responsibility to help the aged—to treat them; to help them help themselves. And believe me, gentlemen, one of the best ways to understand the problems of the aged is to serve them as a physician.

It has been my experience that the aged want just about the same things that all the rest of us do: to be part and parcel of their environment; to feel that their skills and talents have value, and can still be used; to be productive; to be loved; to belong.

There is no doubt about it: the problems of the aged are far broader than those of health alone.

Consider, for example, the field of employment, where compulsory retirement policies often undermine the individual's ego, his will to live, his feeling of usefulness.

Able and anxious to work, he frequently finds his abilities no longer in demand. Unnecessarily placed on the shelf, he feels as if he has been cashiered out of the human army without rank, weapons, medals, or identification.

The public fails to realize that the older citizen continues to have many special needs—In the field of housing; in recreation; in finding acceptance and understanding within the community. He also needs preparation in advance, if his added years of life are to be full and rewarding.

These are not health problems, but they bear on health. And until society recognizes this, it will continue to consider in a piecemeal, hit-or-miss way a problem that requires a broad, total approach.

Concern for these problems animates all thoughtful people.

I can assure you that the doctors of the country are concerned.

For they know, as well as any group, that behind the array of statistics are individual men and women —that while each human being is alike, each is also very different.

And so when physicians hear broad statements about the problems of the aged, when they are asked to consider the across-the-board solutions that are proposed, they tend to apply the acid test of personal experience.

Would these proposed solutions really work? Would they really help the people whom the doctor serves, the individual patients whose problems and needs he knows so intimately?

It is by this yardstick that the physician measures his reply. And it is by this yardstick that the members of the medical profession have formulated their position with respect to H. R. 4700 and similar bills.

I would like to discuss some of the fundamental reasons why we believe that this proposed legislation is neither practical nor realistic.

Medical care is not susceptible to production-line techniques.

Care for any segment of our population—the aged included—calls for a cooperative attack on the problem by nurses, doctors, hospitals, social workers, insurance companies, community leaders and others. It requires flexibility of medical technique—an ingredient which would unquestionably vanish the moment government establishes a health program from a blueprint calling for mass treatment.

If we abandon the community approach in favor of a rigid national health program we will, in effect, have constructed another Procrustes' bed. The mythological Procrustes, you will remember, developed a bed that was just the right size for everybody. There was only one trouble with it:

Procrustes, instead of altering the bed to fit the person, altered the person to fit the bed.

He accomplished this feat of legerdemain by trimming off the legs of the tall, and stretching his shorter victims on the rack.

I am sure we all agree that it is sounder to tailor the bed to fit the patient.

In the case of the aged, their health problem primarily involves acute illness and the so-called degenerative diseases. In a very large percentage of cases, the main need is not for an expensive hospital stay or a surgical operation, but for medical care at home or in the doctor's office. In other cases, the important requirement is nursing care in the patient's home, or the home of relatives. And in still others, custodial care in a nursing home or public facility may be the only answer. The point is that the medical needs of this particular segment of the aged are subject to countless variations. Any workable system of care must be tailored to meet these variations. An example of a faulty program is the mass attack approach that has been forced on medicine in the handling of the mentally afflicted. They are removed from society but their medical problems have not been solved.

If H. R. 4700 were enacted, it would mean that the Federal government would finance the health care of OASDI beneficiaries through compulsory and earmarked taxes; the Federal government would control disbursement of funds; the Federal government would determine the benefits to be provided; the Federal government would set the rates of compensation for hospitals, nursing homes, dentists, and physicians; the Federal government would audit and control the records of hospitals, nursing homes and patients; and the Federal government would promulgate and enforce standards of hospital and medical care.

When government at any level guarantees services which it cannot itself provide, it inevitably tends to control the purveyors of those services. I doubt that anyone here intends or seeks such control, but there is no doubt that it would take place.

Disclaimers notwithstanding, if a single government agency were to buy 10 to 20 per cent of all care in the nation's general hospitals, it would be utterly impossible to limit that agency's power to influence the over-all operation and management of hospitals.

One predictable consequence of such a national program would be the overuse and overcrowding of our hospital facilities. It is certain that a substantial increase in hospital use would result during the first year of this proposed program—simply because a government plan had been put into operation.

As doctors, we believe that patients should be placed in hospitals, nursing homes and other institutions only when necessary. We believe the length of their stay, as well as the therapy rendered, should be dictated only by their medical condition and not by limitations of legislation or regulations.

The problem is far more than a matter of economics, or even of medical technique. For we must also deal with the human spirit, which flourishes best in those who are determined to stay in the mainstream of day-to-day living.

H. R. 4700 would have further bad effects.

—It would curb community incentive to support hospitals, for the tendency would be to shift this responsibility from the shoulders of private and local governmental sources to the already overburdened shoulders of the Federal government.

—It would discourage, at the community level, the freedom to experiment with new techniques, such as home care programs, day hospital service, homemaker services, progressive patient care, and new concepts for treatment through outpatient departments and doctors' offices. And it is at the community level that such innovations are developed and made to work.

—It would discourage families from taking care of their own.

—It would restrict beneficiaries in their choice of hospital and physician. For only those physicians, and those hospitals and nursing homes entering into agreements with the Federal government, would participate.

—The professional relationship between the doctor and his patient—the basis of all effective health care—would be severely handicapped. Government regulation would be imposed on the physician, and on the patient as well, bringing a third and intruding party between them. Required conformance to administrative regulations could also hamper the physician from prescribing treatment which, in his professional opinion, was indicated.

—It would discourage the individual approach to patient care. When this has been disregarded in the past, the result has been mass tragedy rather than mass cure.

—It would attempt to chart a health program for the aged without accurate knowledge of the problem's dimensions. The statistics presently available on the subject are neither conclusive nor complete.

To use them as the basis for so far-reaching a program is akin to prescribing for the patient without first making a diagnosis.

Basically, H. R. 4700 simply proposes a form of national compulsory health insurance. For the moment, it would be limited in scope; however, there are many who are testifying before this Committee this week who admittedly seek to extend the program to every segment of the population. It should be remembered in this connection that, if the Federal government at some future date adopts a medical care program for the total population, it will be assuming a medical bill of more than $20 billion annually. A report published by the Department of Health, Education and Welfare, based on 1957 statistics, indicates that private health care costs approximate $15 billion and that public and philanthropic costs amount to about $5 billion annually.

The bill would establish a dangerous precedent. Instead of cash benefits, it proposes service benefits irrespective of need. In effect, the Federal government would furnish the beneficiary with compulsory hospital and surgical insurance whether he needed it or not, whether he wanted it or not.

In this connection, let me say that the A. M. A. has never opposed the Social Security Act per se. H. R. 4700 is, however, a major and dangerous deviation from the original concept of the system.

We must also face the fact that any single program of health care for the aged should not embrace every aged person. The pending bill would cover millions of people who do not need or want government medicine.

Further, it is a misconception to think that this measure would aid those who receive Public Assistance, the vast majority of whom are not covered by Social Security. These indigent are now receiving their medical care through welfare programs. Aside from the help they get from many private, fraternal and religious organizations, the indigent now receive more than $4 billion annually in federal and state aid for medical and other expenses.

I should like to comment briefly on what this proposed legislation would cost.

It would be staggeringly expensive.

The costs of this program during its first and second years have been estimated as in excess of $2 billion a year, a figure which can be expected to increase during the ensuing years.

There is absolutely no way of predicting the cost of H. R. 4700 in the years ahead. These programs expand. They never contract. And once they are on the books, they are there to stay.

Yet the problem of financing health services for the aged is a temporary, not a permanent one. As Dr. Larson indicated, voluntary health insurance is making tremendous progress, through expanded coverage and broader protection.

Dozens of different type policies are now available. Among them are policies guaranteed renewable for life; policies to cover those now over 65; coverages that will continue after retirement; and group policies that may be converted to individual coverage upon termination of employment.

Much of this progress has been made in just a few years. This indicates that the hospital costs of our aged are being met, in a large measure, by prepayment plans and insurance, as they steadily gain experience in this relatively new field of coverage.

Much progress is also being made in the development of new and improved facilities specially tailored to the particular health requirements of the older citizen.

As a part of this program, the A. M. A. has supported a loan program of the F. H. A. type for non-governmental hospitals and nursing homes, whether of a non-profit or proprietary nature. It has also recommended changes in the Hill-Burton Act to help the individual states earmark more money for non-profit nursing homes.

The A. M. A. continues to back further experiments in progressive hospital care; home care programs; and homemaker services, all of which have the common purpose of improving the quality of medical care by reducing the length of hospital and nursing home confinement through the earlier discharge of patients.

The record shows that sustained and heartening progress is being made throughout the United States toward meeting the needs of our older citizens promptly and positively.

I do not have the time to specify here the details of the massive job that is being done. The fact is that voluntary methods—supported by the cooperative effort of many thousands of our citizens—are meeting the challenge and will continue to meet the challenge, given the continued opportunity.

So that this Committee has at its disposal the American Medical Association's six-point program for older citizens, we are appending a discussion of that program which I had the privilege of giving last month before the U. S. Senate Sub-committee on the Problems of the Aged and Aging.

In closing, one fact seems to me to be crystal clear:

The health professions and other private voluntary groups are meeting the challenge. We believe that the same people who made this the healthiest nation in the world's history, and helped bring the gift of longer life to millions of Americans, are equipped to meet the problem of caring for the health of our older citizens.

Gentlemen, this concludes my formal statement. It is our sincere recommendation that H. R. 4700, 86th Congress, not be favorably considered by this Committee.

Dr. Larson and I will be glad to answer any questions you may have.

LETTER ON AIR POLLUTION

June 26, 1959

Kenneth A. Roberts, Chairman
Health and Safety Subcommittee
Interstate and Foreign Commerce Committee
House of Representatives
Washington 25, D. C.

Dear Mr. Chairman:

I should like to take this opportunity on behalf of the American Medical Association to respectfully submit for your consideration our views on H. R. 2347 and S. 441, 86th Congress, which we understand are now pending before your Committee.

It is our understanding that these bills would extend the duration of the Air Pollution Control Act beyond June 30, 1960. H. R. 2347 would extend the law until June 30, 1965, whereas S. 441 would extend the law until June 30, 1964.

Before commenting on the specific bills, I should like to refer to the general subject of air pollution briefly, which has been defined by our Council on Industrial Health as an excessive atmospheric concentration of foreign matter that may adversely affect the well-being of a person or cause damage to property. Although a health hazard need not be demonstrated to establish the need for the control of air pollution, our interest in this subject is mainly with respect to the relationship of air pollution to health.

Although a number of scientific investigations of air pollution have recently been completed and others are currently being conducted, there are special limitations which make this type of investigation unusually difficult. Experimental studies of the health effects of these pollutants, singly and in combinations, must be conducted in exposure chambers in the laboratory to evaluate the synergistic effects they have upon one another. Observations must be made of the effects on the health of workers in industry exposed to various substances which pollute the air of their work place and which may pollute the air of the surrounding community. However, most productive are epidemiologic and clinical studies of the effects upon the health of the population of a community produced by pollutants in the atmosphere, existing as they do in combinations and affected as they are by sunlight and atmospheric conditions.

It is apparent that future research on the subject of air pollution and its relation to health is highly desirable. We believe that the Air Pollution Control Act which was enacted in 1955 represents a proper approach to the problem. The philosophy of the Act recognizes the primary responsibility of state and local governments in controlling air pollution. Within the framework of a coordinated national program, established under the direction of the Surgeon-General of the United States Public Health Service, we believe there is sufficient flexibility to stimulate the initiative of local agencies and to permit states and communities to deal with the phases of the air pollution problem most important to them. Although the interest of the federal government in the subject of air pollution may not be a permanent one, we feel that sufficient federal responsibility can still be demonstrated to justify the appropriation of limited federal funds in support of research activities in this field for an additional period of time.

The American Medical Association, therefore, recommends that your Committee give favorable consideration to H. R. 2347 and S. 441, 86th Congress. I respectfully request that the foregoing comments on behalf of the American Medical Association be included in and made part of the record of hearings on these bills.

Sincerely yours,
F. J. L. Blasingame, M.D.
Executive Vice-President

NATIONAL MEETING ON MEDICAL ASPECTS OF SPORTS

A National Conference on the Medical Aspects of Sports is being planned to immediately precede the clinical sessions of the American Medical Association at Dallas, Texas, Nov. 30, 1959. The Conference, to be held under the auspices of the A. M. A.'s Committee on the Medical Aspects of Sports (formerly the Committee on Injury in Sports) will be open to athletic directors, coaches, and trainers as well as interested physicians.

The program, to include a wide variety of subjects relating to the health aspects of athletics, will cover the general areas of the physiology and pharmacology of exercise, the training and conditioning of the athlete, and the prevention and treatment of injuries.

Papers to be presented include "Amphetamine Sulfate and Athletic Performance, II Subjective Responses," "A Medical Program for High School Football," "Exercise and the Oxygen Debt," "The Biodynamic Potential of the American Male," "Exercise and the Kidney," "The Pathology of Trauma," and many other subjects to be announced later. Two panels, one covering "The On-Field Responsibilities of the Team Physician" and the other dealing with "The Prevention of Head Injury in the Athlete" are scheduled.

The date and place of the conference (Nov. 30, 1959, in Dallas) were selected so that physicians could conveniently combine attendance with participation in the A. M. A. clinical sessions. Those who wish to receive future announcements concerning the conference may address the Committee on the Medical Aspects of Sports at the A. M. A. offices in Chicago.

Postgraduate Courses for Physicians

Compiled by the Council on Medical Education and Hospitals for the Period Sept. 1, 1959, to Aug. 31, 1960[1]

The data in the following list of postgraduate courses have been compiled by the staff under the supervision of Dr. Glen R. Shepherd, Assistant Secretary of the Council on Medical Education and Hospitals. The Council desires to express appreciation to the officers of the medical schools, hospitals, and medical societies who have cooperated in furnishing the information essential to the preparation of this report.

Walter S. Wiggins, M.D., Secretary
Council on Medical Education and Hospitals

INTRODUCTION

The fifth annual listing of postgraduate courses in this country for physicians appears in the following pages of The Journal. This listing is for the period Sept. 1, 1959, to Aug. 31, 1960. The annual list replaces the semiannual lists that appeared previously.

The purpose of the single annual listing is to bring together in one place information secured about postgraduate courses to be offered in the year ahead. It is the consensus that such a single annual listing provides a reference that potential physician-enrollees are more likely to consult than do single notices in random issues of The Journal. Further, such a list encourages long-range advance planning of the courses that in the opinion of the Council and other medical educators is likely to contribute significantly to improvement in the quality of the courses so planned. The general acceptance of a single annual listing will make possible the publication of a selective listing of the more educationally meritorious programs when a suitable appraisal mechanism has been thoroughly tested. Such studies are now under way. Therefore, it is expected that supplementary notices of postgraduate courses will not be published in The Journal.

Postgraduate medical education courses consist of planned activities for doctors of medicine intended to refresh practicing physicians in the various aspects of their basic medical education, to provide information on new developments in medicine, and to stimulate further educational efforts by the participants. Such courses are not designed to provide the lengthy intensive education required for initial training for a specialty. This is graduate medical education, usually comprising residency training or fellowships. Postgraduate courses are shorter than graduate education programs.

This list of postgraduate courses was prepared from the unappraised and unevaluated replies to Council questionnaires by American medical schools, hospitals, and the various national, state, and specialty medical societies. This list is printed simply to provide for those physicians seeking postgraduate courses a point of departure through which further information can be obtained by writing to the institution or organization listed under Location. Inquiries should be made before traveling to any course listed, because dates, time arrangements, and fees are subject to change. Sponsors of courses having numerical limitation of registration must restrict enrollment, often on the basis of order of application. Courses for which there is insufficient advance registration may be canceled. Such inquiry of the sponsor is especially urged about courses scheduled for 1960, on which final information may not have been available to the sponsor at the time this list was prepared.

Though the educational values of medical society meetings and conventions as well as hospital staff and departmental meetings can be very real and worthwhile, such meetings are not usually listed here as postgraduate courses. Lists of meetings are to be found periodically elsewhere in The Journal.

Many of the courses have co-sponsors to whom specific credit cannot be given because of space limitations. It is expected that the institution or organization sponsoring the course has provided such co-sponsor recognition to its registrants.

Under each category in the following list, the order of arrangement of the courses is alphabetically, first by states, second by cities within state, third by the institutions and organizations within the cities, and last by date of course where several courses in that category are offered by the same institution or organization.

Although the list may indicate that a course is designed primarily for specialists in that category, many such courses are open to any physician, so specific inquiry should be made of the institution listed.

One of the categories has a special use in addition to its usual denotation. In the General Medicine category are listed those courses having subjects embracing several fields, such as a course on the management of mass casualties or the Summer School of Alcohol Studies.

Following the list of courses appears a geographical cross-reference alphabetically by state and city of the categories under which courses so located are listed. This should assist doctors seeking courses in a certain location to find their listing.

KEY

Designed For

G—General practitioners
S—Specialists
B—Both
Lim—Enrollment limited to specified number with number stated; i. e., Lim 20, meaning enrollment limited to 20 in the course. If it is repeated, another 20 could be accommodated

Type

IC—Intensive continuous
II—Intensive intermittent
CC—Circuit course
PT—*Postgraduate traineeship**
HS—Home study
HS (C)—Home study by correspondence
HS (R)—Home study by radio
O—Other

Time Arrangement

C—Continuous or concentrated (e. g., as every day for five days)
I—Intermittent (e. g., every Thursday for six weeks)

Methods of Education

AV—Audiovisual aids (movies, slides, models)
BR—Bedside rounds
Clin C—Clinical conference
Dem—Demonstrations other than of patients
EPP—Enrolee performs procedure
LC—Live clinic
Lab—Laboratory work (including cadaver dissection and dog surgery where applicable)
Lec—Lecture
O—Open question periods
PD—Patient demonstration
Pan—Panel discussion
PT—Postgraduate traineeship*
R—Radio or telephone
Sem—Seminar
Surg—Operative human surgery
TV—Television

*A postgraduate traineeship *for practicing physicians* is an individually arranged residency-type postgraduate educational experience in a hospital usually with residents in that field. It differs from a residency or fellowship in the following ways: 1. It is not primarily intended to provide training for entering specialty practice or, in itself, to qualify for specialty board certification. 2. Therefore, it is of shorter duration than a year. 3. It usually does not provide either a stipend or housing, and it may exact a fee from the physicians in such training. 4. It may not (or may) involve direct patient responsibility.

Postgraduate Lectures in Anesthesiology—Basic Science and Clinical	Maine Medical Center 22 Bramhall St., Portland, Me.	G	II	Sem, Lec, O, AV	15	10/16/59	5/60	I; 15 sessions 1 hr. twice monthly, Fridays	Nil
Regional Anesthesia	University of Missouri School of Medicine 807 Stadium Rd., Columbia, Mo.	G Lim 15	IC	Lab, PD, LC, BR, Clin C, Sem, Lec, Pan, O, EPP	30	Arranged		C; 5 days	100
One Day Postgraduate Seminar in Anesthesiology	Department of Postgraduate Medical Education, Seton Hall College of Medicine and Dentistry 31 Clinton St., Newark 2, N. J.; course at Cherry Hill Inn, Dover Township, N. J.	S Lim 40	IC	Sem, Lec, Pan, O, AV	8	3/26/60	3/26/60	C; 1 day	Unknown

Anesthesia	University of Buffalo School of Medicine 3435 Main St., Buffalo	G Lim 12	IC	PD, Sem, Lec, Pan, O, AV	39	4/ 4/60	4/ 9/60	C; 5½ days	75
Anesthesia and Analgesia in Obstetrics	New York Medical College Metropolitan Medical Center Fifth Ave. at 106th St., New York 29	G	IC	PD, Sem, Lec, AV, EPP	15	Arranged		C; 5 days	125
Anesthesiology—Special Techniques in Anesthesia	New York Medical College Metropolitan Medical Center Fifth Ave. at 106th St., New York 29	G	IC	PD, Sem, Lec, AV, EPP	15	Arranged		C; 5 days	125
Endo-Tracheal Techniques in Anesthesia	New York Medical College Metropolitan Medical Center Fifth Ave. at 106th St., New York 29	G	IC	PD, Sem, Lec, AV, EPP	15	Arranged		C; 5 days	125
Applied Anesthesiology	New York Polyclinic Hospital 315 W. 50th St., New York 19	G Lim 10	IC	Lab, PD, BR, Lec, O, AV	480	4/ 1/60 10/ 1/60	6/30/60	C; 72 days	300
Postgraduate Training in Anesthesia for the Part-time Anesthetist	New York State Society of Anesthesiologists 131 W. 11th St., New York 11; course at various hospitals throughout New York State	G	O	Lab, PD, LC, BR, Clin C, Sem, Surg, Lec, EPP	Variable	Arranged		Variable	Nil
#512-Anesthesiology (For Specialists)	New York University Post-Graduate Medical School 550 First Ave., New York 16	S Lim 3	II	PD, Clin C, Surg, Lec, EPP	70	9/59	9/60	I; 10 days, any Monday	175
#513-Regional Anesthesiology	New York University Post-Graduate Medical School 550 First Ave., New York 16	G Lim 16	IC	Lab, PD, Lec	42	9/14/59 1/11/60	9/19/59	C; 6 days	135
#511-Anesthesiology: Endotracheal and Related Methods	New York University Post-Graduate Medical School 550 First Ave., New York 16	S Lim 4	IC	Lab, PD, Clin C, Surg, Lec, EPP	35	9/28/59 1/25/60 3/21/60	10/ 3/59	C; 5 days	135
Inhalation Anesthesia	McKesson Anesthesia Associates 2228 Ashland Ave., Toledo, Ohio; course at various Toledo Hospitals	G Lim 2	IC	PD, Clin C, Sem, Surg, Lec, O, EPP	140	Arranged		C; 25 days	250
Recent Advances in the Physiological Aspects of Anesthesia	University of Pennsylvania Graduate School of Medicine 237 Medical Lab. Bldg., Philadelphia	G Lim 125	IC	Sem, Lec, Pan, O	Unknown	2/ 8/60	2/10/60	C; 3 days	75
Anesthesia Refresher Course	University of Texas Postgraduate School of Medicine 1400 Outer Belt Drive Houston 25, Tex.; course at Scott and White Memorial Hospital, Temple, Tex.	G Lim 2	IC	PD, BR, Sem, Surg, Lec, O, EPP	176	9/ 7/59	10/ 3/59	C; 24 days	25
Fifth Annual Course in Anesthesiology-Principles and Application	University of Texas Postgraduate School of Medicine 1400 Outer Belt Drive Houston 25, Tex.; course at University of Texas M.D. Anderson Hospital and Tumor Institute, Houston, Tex.	B Lim 270	IC	Lec, Pan, O, AV, TV	20	3/ 9/60	3/11/60	C; 3 days	45
Postgraduate Refresher Course in Anesthesiology	University of Texas Postgraduate School of Medicine 213 W. Avenue G, Temple, Tex.; course at Scott and White Memorial Hospital; Scott, Sherwood and Brindley Foundation, Temple, Tex.	G Lim 1	IC	PD, BR, Sem, Surg, Lec, EPP	176	First Monday in each mo.	Last Saturday in each mo.	C; 24 days	25

BASIC SCIENCES
(See also Clinical Pathology)

Correlation of Medical Basic Sciences	St. Mary's Hospital 2200 *Hayes St., San Francisco*	G Lim 400	II	Clin C, Lec, O	20	9/ 1/59	7/ 1/60	I; 20 sessions 1 hr. twice monthly, Saturdays	Nil
Principles and Techniques of Tissue Culture	Dr. Mary S. Parshley Columbia University, College of Physicians and Surgeons 630 W. 168th St., New York 32; course at University of Colorado Medical School, Denver	Medical Research Personnel Lim 30 (15 active partic.)	IC	Lab, Sem, Lec, EPP	114	Summer 1960		C; 26 days	100
4th Annual Conference on Quantitative Studies of the Growth and Genetic Processes in Mammalian Cells	University of Colorado School of Medicine 4200 E. Ninth Ave., Denver 20; course at Stanley Hotel, Estes Park, Colorado.	S Lim 50	IC	Sem, Lec, O, AV	32	8/31/59	9/ 3/59	C; 4 days	5
Microbiology 210—Diagnostic Medical Mycology	Assistant Dean of Postgraduate Medical Education Yale University School of Medicine 333 Cedar St., New Haven, Conn.	S	IC	Lab, Sem, O, EPP	150	Arranged		C; 25 days	100
Orthopedic Basic Science	Northwestern University Medical School 303 E. Chicago Ave., Chicago 11	S Lim 16	IC	Lab, PD, LC, BR, Clin C, Sem, Lec	750	7/ 1/60	12/31/60	C; 120 days	600

BASIC SCIENCES—Continued

Title of Course	Location	Designed For	Type	Methods of Education	Total Hours	Starting Date	Ending Date	Time Arrangement	Fee
Clinical Traineeship in Microbiology	University of Kansas Medical Center 39th and Rainbow Blvd., Kansas City, Ks.	G Lim 1	PT	Lab, BR, Clin C, Sem, Lec, O, AV, EPP		Arranged		Arranged	50 mo. Kansas residents; 100 mo. nonresidents
Histochemistry	University of Kansas Medical Center 39th and Rainbow Blvd., Kansas City, Ks.	S Lim 18 1st. wk. Lim 24 2nd. wk.	IC	Lab, Sem, Lec, O, AV	84	6/ 6/60	6/18/60	C; 12 days	75 one week; 150 two weeks
Basic Sciences As They Apply to The Practice of Medicine	Postgraduate Committee, University of Maryland School of Medicine 522 W. Lombard St., Baltimore	B Lim 100	II	Unknown	12	1/ 6/60	5/26/60	I; 21 sessions 2 hr. weekly, Wednesdays	50
Modern Research Methods in Biology and Medicine	Director of the Summer Session Massachusetts Institute of Technology Cambridge 39, Mass.	S	IC	Lab, Lec, AV	50	July or August/60		C; 10 days	Not yet determined
Basic Sciences with Clinical Application	University of Michigan Medical School Department of Postgraduate Medicine University Hospital, Ann Arbor, Mich.	Residents of Affiliated Hospitals; Open to Practitioners B Lim 40	PT	Lab, PD, LC, Clin C, Lec, O, AV		9/28/59	6/ 4/60	8 mo.	500
Bacteriology with Clinical Application	University of Michigan Medical School Department of Postgraduate Medicine University Hospital, Ann Arbor, Mich.	B Lim 40	IC or PT	Lab, PD, Clin C, Lec, O, AV	60	1/ 4/60	1/16/60	C; 10 days	50
Biophysics with Clinical Application	University of Michigan Medical School Department of Postgraduate Medicine University Hospital, Ann Arbor, Mich	B Lim 40	IC or PT	Lab, Clin C, Lec, O, AV	60	1/18/60	1/30/60	C; 10 days	50
Biochemistry with Clinical Application	University of Michigan Medical School Department of Postgraduate Medicine University Hospital, Ann Arbor, Mich	B Lim 40	IC or PT	Lab, PD, Clin C, Lec, O, AV	90	2/15/60	3/ 5/60	C; 15 days	75
Physiology with Clinical Correlation	University of Michigan Medical School Department of Postgraduate Medicine University Hospital, Ann Arbor, Mich.	B Lim 40	IC or PT	Lab, PD, Clin C, Lec, O, AV	60	3/ 7/60	3/19/60	C; 10 days	50
Pharmacology with Clinical Application	University of Michigan Medical School Department of Postgraduate Medicine University Hospital, Ann Arbor, Mich.	B Lim 40	IC or PT	Lab, PD, Clin C, Lec, Pan, O, AV	60	3/21/60 3/26/60	4/ 4/60	C; 10 days	50
Biochemistry	Department of Postgraduate Medical Education, Seton Hall College of Medicine 31 Clinton St., Newark, N. J.; course at Martland Medical Center, Newark, N. J.	G Lim 40	II	Lec, O, AV	15	Fall/59		I; 10 sessions 1½ hr. weekly, Wednesdays	50
Physiology PM 33—Seminar in Selected Topics in Gastrointestinal Physiology	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital, New York 29	S	II	Sem, Lec, O, AV	70	10/ 1/59	6/ 1/60	I; 70 sessions 1 hr. twice weekly, Mondays, Fridays	100
Physiology PM 32—Normal and Pathological Physiology	Columbia University College of Physicians and Surgeons 630 W. 168 St., New York 32; course at Mount Sinai Hospital, New York 29	G	II	Lec, O, AV	52	10/ 7/59	4/13/60	I; 26 sessions 2 hr. weekly, Wednesdays	150
Sensory Physiology—Physiology of the Senses With Emphasis Upon Receptors	New York Medical College Flower and Fifth Ave. Hospitals Fifth Ave., and 106th St., New York	S Lim 10	II	Lab, Dem, Lec	10	Arranged		I; 10 sessions 1 hr. weekly, Wednesdays	100
Physiology of Reproduction	New York Medical College Flower and Fifth Ave. Hospitals Fifth Ave., and 106th St., New York	S Lim 20	II	Sem, Lec	12	Arranged		I; 6 sessions 2 hr. ea.	75
Physiology of the Endocrine System—Survey of Recent Advances With Respect to Basic Concepts	New York Medical College Flower and Fifth Ave. Hospitals Fifth Ave., and 106th St., New York	G Lim 10	II	Lab, Lec, AV	16	9/14/59	11/14/59	I; 8 sessions 2 hr. weekly, Mondays	75
Review of Embryology—Practical Considerations in Developmental Anomalies	New York Medical College Flower and Fifth Ave. Hospitals Fifth Ave., and 106th St., New York	G Lim 15	IC or II	Lec, AV	15	2/ 4/60	4/ 7/60	C; or 1½ hr. Intermittent by arrangement	100
Basic Sciences in Medicine and Surgery	New York Polyclinic Hospital 315 W. 50th St., New York 19	G Lim 15	IC	Lab, PD, LC, BR, Clin C, Lec, O, AV	30	4/ 1/60 10/ 1/60	4/ 6/60	C; 5 days	50
2012—Neuroanatomy and Neurophysiology	New York University Post-Graduate Medical School 550 First Ave., New York 16	G Lim 30	II	Lab, Lec	120	9/14/59		I; 36 sessions 3½ hr. thrice weekly, Mondays, Wednesdays, Fridays	375

‡1814—Radiochemical Analysis	New York University Post-Graduate Medical Medical School 550 First Ave., New York 16	G	IC	Lab, Lec, AV	70	11/ 9/59	11/20/59	C; 10 days	100
‡161—Clinical Physiology: The Application of Basic Physiology to Diagnostic and Therapeutic Problems	New York University Post-Graduate Medical Medical School 550 First Ave., New York 16	G Lim 35	II	Clin C, Sem, Lec, O, AV	16	3/ 3/60	4/21/60	I; 8 sessions 2 hr. weekly, Thursdays	60
Human Tumor Transplantation—Heterologous Transplantation of Human Tissues	Sloan Kettering Institute for Cancer Research 410 E. 68th St., New York	M.D.'s and senior research investigators Lim 30	IC	Lab, Sem, Lec, Pan, O, EPP	27	10/ 6/59 3/ 8/60	10/ 9/59	C; 3 days	Nil

CARDIOVASCULAR DISEASE

(See also Chest Disease, Electrocardiography, Internal Medicine)

Twenty-Ninth Annual Professional *Symposium*	Los Angeles County Heart Association 660 S. Western Ave., Los Angeles 5; course at Beverly Hilton Hotel, Beverly Hills, Calif.	G	IC	Sem, Lec, Pan, O, AV	16	10/ 7/59	10/ 8/59	C; 2 days	Unknown
‡873—Cardiac Resuscitation	University of Southern California School of *Medicine Postgraduate* Division 2025 Zonal Ave., Los Angeles 33	G Lim 5	II	Lab, Lec, EPP	2	continuous weekly		I; 1 session 2 hr. weekly, Wednesdays	30 practicing physicians; Nil residents, interns Armed Forces
‡834—Practical Diagnosis and Management of Cardiovascular Diseases	University of Southern California School of Medicine Postgraduate Division 2025 Zonal Ave., Los Angeles 33; course at Hotel Statler and Los Angeles County Hospital	G Lim 100	IC	Lec, Pan, O	21	9/18/59	9/20/59	C; 3 days	65
‡833—Bedside Cardiology	University of *Southern* California School of Medicine Postgraduate Division 2025 Zonal Ave., Los Angeles 33	G Lim 65	II	PD, LC, BR, Clin C, Sem, Lec, Pan, O	21	2/ 4/60	4/21/60	I; 12 sessions 2 hr weekly Wednesdays	65
‡843—Symposium on *Hypertension*	University of Southern California School of Medicine Postgraduate Division 2025 Zonal Ave., Los Angeles 33; course at Hotel Statler, Los Angeles	G Lim 100	O	Lec, Pan, O, AV	7	3/11/60	3/11/60	C; 1 day	25
9th Annual Symposium on Heart Disease—"A Program for Clinicians",	San Diego County Heart Association 3545 Fourth Ave., San Diego, Calif.; course at El Cortez Hotel, San Diego	B	IC	PD, Lec, Pan, O, AV	10½	10/ 5/59	10/ 6/59	C; 1½ days	5
Twenty-Ninth Annual Postgraduate Symposium on Heart Disease	San Francisco Heart Association, Inc. 229 Geary St., San Francisco 2; course at St. Francis Hotel, San Francisco	B	IO	PD, Clin C, Sem, Lec, Pan, O, AV	21	9/30/59	10/ 2/59	C; 3 days	Unknown
Symposium on Heart Disease	*Orange County Heart Association* P. O. Box 1704, Santa Ana, Calif.	G	IC	Surg, Lec, Pan, O, AV	8-10	Spring/60		C; 1 day	12.50
Symposium on Cardiovascular Diseases	Santa Barbara County Heart Association 18 *La Arcada* Court, Santa Barbara, Calif.; course at Biltmore Hotel, Santa Barbara	B Lim 100	IC	Sem, Lec, Pan, O, AV	8	Unknown		C; 1 day	20
Annual Heart Symposium	Sonoma County Heart Association Rosenberg Building, Santa Rosa, Calif.	G	IC	**Lec**, Pan, O, AV	6-8	Fall/59		C; 1 day	15
Western Cardiac Conference	Colorado Heart Association 1636 Logan St., Denver	G	IC	Lec, Pan, O, AV	30	8/15/60	8/19/60	C; 5 days	10 to 30
9th Annual Western Cardiac Conference	University of Colorado School of Medicine 4200 E. Ninth Ave., Denver 20	B	IC	PD, Sem, Lec, Pan, O, AV	40	8/22/60	8/26/60	C; 5 days	Unknown
Heart Symposium (9th Annual)	Indiana University School of Medicine 1100 W. Michigan St., Indianapolis 7	G	IC	Lec, Pan, O, AV	7	2/10/60	2/10/60	C; 1 day	Nil
Diagnosis and Treatment of Heart Disease, Including Special Tests	Indiana University School of Medicine 1100 W. Michigan St., Indianapolis 7	G	IC	Lec, Pan, O, AV	11	4/20/60	4/21/60	C; 2 days	20
Midwest Cardiac Conference	Iowa Heart Association 2100 Grand Ave., Des Moines; course at State University of Iowa Iowa City	G	IC	Clin C, Lec, Pan, O, AV	10	11/13/59	11/15/59	C; 3 days	Nil
Cardiology	University of Kansas Medical Center 39th and Rainbow Blvd., Kansas City, Ks.	G Lim 10	PT	Lab, BR, Clin C, Sem, Lec, O, AV, EPP		9/15/59	6/15/60	9 mo.	600
The Heart: Rheumatic and Congenital Heart Disease	University of Kansas Medical Center 39th and Rainbow Blvd., Kansas City, Ks.	G	IC	PD, LC, Clin C, Sem, Lec, Pan, O, AV	28	1/18/60	1/21/60	C; 4 days	75
Clinical Traineeship in Cardiovascular Disease	University of Kansas Medical Center 39th and Rainbow Blvd., Kansas City, Ks.	G Lim 2	PT	Lab, BR, Clin C, Lec, O, AV, EPP	120	2/ 1/60 3/ 1/60	2/29/60	30 days	200
Cardiovascular Disease	Harvard Medical School 25 Shattuck St., Boston; course at *Massachusetts General Hospital*, Boston 14	S Lim 12	IC	Lab, PD, LC, BR, Clin C, Lec, O	35-40 per week	10/ 1/59	5/31/60	C, unknown	800

Title of Course	Location	Designed For	Type	Methods of Education	Total Hours	Starting Date	Ending Date	Time Arrangement	Fee
Orthopedics—Surgery and Fractures	Department of Continuing Education in Medicine and Health Sciences University of California Medical Center Second and Parnassus Ave., San Francisco; course at Mt. Zion Hospital, San Francisco	G Lim 35	IC	PD, Lec, Pan, O, AV	14	9/59		C; 2 days	50
Management of Common Orthopedic Disorders in Children	Department of Continuing Medical Education in Medicine and Health Sciences University of California Medical School Second and Parnassus Ave., San Francisco 22; course at Children's Hospital, San Francisco	G Lim 100	IC	Lec, Pan, O, AV	7	1/23/60	1/23/60	C; 1 day	12.50
Instructional Course Program	American Academy of Orthopedic Surgeons 116 S. Michigan Ave., Chicago	G	IC	PD, Clin C, Sem, Lec, Pan, O, AV	9	1/24/60	1/27/60	C; 4 days	15
Orthopedics	Indiana University School of Medicine 1100 W. Michigan St., Indianapolis 7	G	IC	PD, Lec, Pan, O, AV	7	2/17/60	2/17/60	C; 1 day	10
Clinical Traineeship	Tulane University School of Medicine 1430 Tulane Ave., New Orleans	Unknown Lim 2	PT	PT	Full time	Arranged	1 week or more later		25 per week
Surgery of the Hand	Tulane University School of Medicine 1430 Tulane Ave., New Orleans	G Lim 50	IC	PD, Sem, Lec, Pan, O, AV	20	3/ 3/60	3/ 5/60	C; 2½ days	25
Orthopedic Surgery 1	Harvard Medical School 25 Shattuck St., Boston; course at Children's Hospital, Boston	S Lim 2	IC	Lab, PD, LC, BR, Sem, Surg, Lec	Variable	Arranged		C; Arranged	200 for 3 mo.
Orthopedic Surgery 2	Harvard Medical School 25 Shattuck St., Boston; course at Massachusetts General Hospital, Boston	S Lim 2	IC	Lab, PD, LC, BR, Sem, Surg, Lec	Variable	Arranged		C; Arranged	800 for 12 mo.
Orthopedic Surgery PM 81—Foot Disabilities: a Survey of the Diagnostic and Therapeutic Problems of the Foot	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32 course at Hospital for Joint Diseases New York 35	S	IC	PD, Lec, O, AV	18	10/ 1/59	10/ 3/59	C; 3 days	100
Orthopedic Surgery PM 80	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32 course at Hospital for Joint Diseases New York 35	G	IC	PD, Lec, O, AV	36	10/12/59	10/17/59	C; 6 days	100
Orthopedic Surgery PM 1—Orthopedic Surgery, Musculoskeletal Disease & Injury	Columbia University College of Physicians and Surgeons 630 W 168th St., New York 32 course at Columbia-Presbyterian Medical Center, New York 32	S	IC	Lec, O, AV	35	11/ 9/59	11/13/59	C; 5 days	100
Basic Engineering for Orthopedic Surgeons	New York Medical College Flower and Fifth Ave. Hospitals Fifth Ave. and 106th St., New York	S Lim 10	II	PD, BR, Lec	12	Arranged		I; 12 sessions 1 hr. ea.	100
Orthopedics of the Foot	New York Medical College Flower and Fifth Ave. Hospitals Fifth Ave. and 106th St., New York	S Lim 5	II	PD, LC, BR, Surg, Lec	24	Arranged		I; 8 sessions, 3 hr. weekly, day by arrangement	100
581—Orthopedics for the General Practitioner	New York University Post-Graduate Medical School 550 First Ave., New York 16	G Lim 20	II	PD, BR, O, AV, EPP	16	10/ 6/59	12/ 1/59	I; 8 sessions 2 hr. weekly, Tuesdays	45
582—Orthopedic Aspects of the Treatment of Rheumatic Disorders	New York University Post-Graduate Medical School 550 First Ave., New York 16	G Lim 20	II	PD, BR, Clin C, Lec, O, AV	20	10/ 7/59	12/ 9/59	I; 10 sessions 2 hr. weekly, Wednesdays	50
584—Orthopedics in General Practice	New York University Post-Graduate Medical School 550 First Ave., New York 16	G Lim 20	IC	PD, BR, O, AV, EPP	21	2/17/60	2/19/60	C; 3 days	55
585—Orthopedic Aspects of the Treatment of Rheumatic Disorders	New York University Post-Graduate Medical School 550 First Ave., New York 16	G Lim 20	II	PD, LC, BR, Clin C, Lec, O, AV	21	3/15/60	3/29/60	I; 3 sessions 7 hr. weekly, Tuesdays	50
Basic Science Conference for Orthopedic Surgeons	Ohio State University, College of Medicine 11th and Neil Aves., Columbus 10, Ohio	S	IC	Sem, Lec	16	3/ 9/60	3/10/60	C; 2 days	Unknown

OTOLARYNGOLOGY

(See also Anatomy, Pathology)

Title of Course	Location	Designed For	Type	Methods of Education	Total Hours	Starting Date	Ending Date	Time Arrangement	Fee
Ear, Nose and Throat	Department of Continuing Education in Medicine and Health Sciences University of California Medical Center Los Angeles 24	G	IC	Sem, Lec, Pan, O, AV	12	11/13/59	11/14/59	C; 2 days	50
Ear-Nose-Throat	Department of Continuing Education in Medicine and Health Sciences University of California Medical Center	G Lim 10	IC	PD, LC, Lec, Pan, O, AV, EPP	14	Spring/60		C; 2 days	40

Clinical Otolaryngology	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	G Lim 4	PT	Lab, PD, LC, BR, Clin C, Surg, O	60	Arranged	2 wk. later	10 days	50
Fellowship Fenestration Surgery	Northwestern University Medical School 303 E. Chicago Ave., Chicago 11	S Lim 2	IC	Lab, PD, LC, BR, Clin C, Sem, O, Lec	960	Arranged		C; 80 days	500
Basic Otologic Surgery	Northwestern University Medical School 303 E. Chicago Ave., Chicago 11	S Lim 10	IC	Lab, PD, LC, BR, Clin C, Sem, Lec	200	2/ 1/60	3/ 4/60	C; 5 weeks	800
Annual Otolaryngologic Assembly—Current Trends in Otolaryngology	University of Illinois College of Medicine 1853 W. Polk St., Chicago 12	S Lim 40	IC	Lab, PD, Clin C, Sem, Lec, Pan, O, AV	75	9/18/59	9/26/59	C; 9 days	125
Bronchoesophagology	University of Illinois College of Medicine 1853 W. Polk St., Chicago 12	S 15	IC	Lab, PD, LC, BR, Clin C, Sem, Surg, Lec, O, AV	84	11/ 9/59	11/21/59	C; 12 days	210
Anatomical and Clinical Otolaryngology	Indiana University School of Medicine 1100 W. Michigan St., Indianapolis 7	S	IC	Lab, PD, Lec, Pan, O, AV, EPP	100	4/ 4/60	4/16/60	C; 13 days	250
Clinical Traineeship in Otorhinolaryngology	University of Kansas Medical Center 39th and Rainbow Blvd., Kansas City, Ks.	S Lim 1	PT	Lab, BR, Clin C, Sem, Lec, O, AV, EPP		Arranged		Arranged	50 mo. Kansas residents; 100 mo. non-residents
Otolaryngology	University of Kansas Medical Center 39th and Rainbow Blvd., Kansas City, Ks.	S	IC	Clin C, Lec, Pan, O, AV	17	4/ 6/60	4/ 8/60	C; 3 days	40
Clinical Traineeship	Tulane University School of Medicine 1430 Tulane Ave., New Orleans	Unknown Lim 2	PT	PT	Full time	Arranged	1 week or more later		25 per week
Otolaryngology for General Practitioners	Tulane University School of Medicine 1430 Tulane Ave., New Orleans	G Lim 25	IC	Sem, Lec, Pan	16	4/21/60	4/22/60	C; 2 days	25
Otology	University of Michigan Medical School Department of Postgraduate Medicine University Hospital, Ann Arbor, Mich.	S Lim 60	IC	Lec, O, AV	18	4/21/60	4/23/60	C; 3 days	50
Otolaryngology for Specialists	Continuation Medical Education 1342 Mayo Memorial University of Minnesota, Minneapolis 14	S	IC	Lec, Pan, O, AV	15	5/23/60	5/25/60	C; 3 days	40
Home Study Course in Otolaryngology	American Academy of Ophthalmology and Otolaryngology 15 Second St., S. W., Rochester, Minn.	S	HS(C)	Assigned reading		9/ 1/59	6/30/60	9 mo.	20
Otorhinolaryngology PM 30—Transmeatal (Endaural) Surgery	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital, New York 29	S Lim 9	IC	Lab, Surg, Lec, O, AV, EPP	80	9/ 8/59 3/28/60	9/19/59	C; 10 days	350
Otorhinolaryngology PM 32—Combined Course in (a) Indirect Laryngoscopy and Voice Rehabilitation and (b) Audiology	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital, New York 29	S	IC	PD, LC, Sem	21 each section	2/ 8/60 (section a) 2/11/60 (section b)	2/10/60	C; 6 days, both sections	75 per section; 150 entire course
Otorhinolaryngology PM 31—Mobilization of Stapes	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital, New York 29	S Lim 6	IC	Lab, PD, Surg	120	4/18/60	5/ 6/60	C; 15 days	500
Otorhinolaryngology PM 33—Rhinoplasty and Otoplasty	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital, New York 29	S Lim 30	IC	Lab, LC, Surg, Lec, O, AV	112	7/16/60	7/29/60	C; 14 days	350
591—Endaural Surgery	New York University Post-Graduate Medical School 550 First Ave., New York 16	S Lim 8	IC	Lab, PD, Sem, Lec, Pan, O, AV, EPP	70	11/ 9/59 2/ 1/60	11/20/59	C; 10 days	275
595—Laryngology and Surgery of the Larynx and Neck	New York University Post-Graduate Medical School 550 First Ave., New York 16	S Lim 10	IC	Lab, PD, LC, Sem, Surg, Lec, Pan, O, AV, EPP	70	1/11/60	1/22/60	C; 10 days	250
592—Audiology	New York University Post-Graduate Medical School 550 First Ave., New York 16	S Lim 15	IC	PD, LC, Clin C, Sem, Lec, Pan, O, AV, EPP	21	2/29/60	3/ 2/60	C; 3 days	60
593—Neuro—Otology	New York University Post-Graduate Medical School 550 First Ave., New York 16	G Lim 10	IC	PD, LC, Clin C, Sem, Lec, Pan, O, AV	21	3/ 3/60	3/ 5/60	C; 3 days	50
Twenty-Fourth Annual Graduate Convention in Otology, Rhinology, and Laryngology—Regional Anatomy and Cadaver Surgery	University of Cincinnati College of Medicine Eden and Bethesda Aves., Cincinnati 19	S Lim 22	IC	Lab, PD, Clin C, Sem, Surg, Lec, O, AV, EPP	45	4/11/60	4/16/60	C; 5½ days	150
Postgraduate Convention—Otolaryngology	Secretary-Treasurer Oregon Academy of Ophthalmology and Otolaryngology Postgraduate Convention 1216 S. W. Yamhill St., Portland 5, Ore.; course at University of Oregon Medical School, Portland 1, Ore.	S	IC	Lec, Pan, O, AV	16	3/11/60	3/12/60	C; 2 days	60; or 90 if combined with Ophthalmology course

Key will be found on page 1938.

OTOLARYNGOLOGY—Continued

Title of Course	Location	Designed For	Type	Methods of Education	Total Hours	Starting Date	Ending Date	Time Arrangement	Fee
ryngology and Laryngeal Surgery	Chevalier Jackson Clinic Temple University Medical Center 3401 N. Broad St., Philadelphia 40	B Lim 10	IC	Lab, PD, LC, Clin C, Sem, Surg, Lec, Pan, O, AV, EPP	80	9/14/59	9/25/59	C; 11 days	250
habilitation of the Laryngectomee	University of Texas Postgraduate School of Medicine 1400 Outer Belt Drive, Houston 25, Tex.; course at University of Texas M. D. Anderson Hospital and Tumor Institute, Houston, Tex.	G also non-physicians	IC or II	PD, Lec, O, AV, EPP	70	6/60	6/60	C; 10 days	Unknown

PATHOLOGY

Title of Course	Location	Designed For	Type	Methods of Education	Total Hours	Starting Date	Ending Date	Time Arrangement	Fee
athology 200—Brain Tumor Registry —Neuropathology	Assistant Dean of Postgraduate Medical Education Yale University School of Medicine 333 Cedar St., New Haven, Conn.	S Neurosurgery, Neurology, and Neuropathology	IC	Sem, O, AV	Arranged	Arranged		Arranged	Arranged
Application of Histochemistry to Pathology	Armed Forces Institute of Pathology 6825 16th St., N.W., Washington 12, D. C.	S Lim 30	IC	Lab, Sem, Lec	35	10/26/59	10/30/59	C; 5 days	Nil
Forensic Pathology	Armed Forces Institute of Pathology 6825 16th St., N.W., Washington 12, D. C.	S Lim 50	IC	Lab, Sem, Lec, Pan, O, AV, TV	35	11/ 8/59	11/13/59	C; 6 days	Nil
Pathology of Diseases of Laboratory Animals	Armed Forces Institute of Pathology 6825 16th St., N.W., Washington 12, D. C.	S Lim 60	IC	Lec	36	12/ 7/59	12/11/59	C; 5 days	Nil
Pathology of the Oral Regions	Armed Forces Institute of Pathology 6825 16th St., N.W., Washington 12, D. C.	B and dentists Lim 100	IC	Sem, Lec, Pan	35	3/14/60	3/18/60	C; 5 days	Nil
Ophthalmic Pathology	Armed Forces Institute of Pathology 6825 16th St., N.W., Washington 12, D. C.	S Lim 50	IC	Lab, Sem, Lec, AV	35	3/28/60	4/ 1/60	C; 5 days	Nil
Refresher Course for Laboratory Medical Officers	Department of the Army Office of the Surgeon General Personnel and Training Division Washington 25, D. C.; course at Walter Reed Army Institute of Research, Washington 12, D. C.	S (Military personnel only) Lim 20	IC	Lab, Sem, Lec, Pan, O, AV, EPP	44	2/ 8/60	2/13/60	C; 6 days	Nil
Cancer Cytology	Cancer Institute at Miami 1155 N. W. 14th St., Miami, Fla.	G	PT	Lab, PD, Sem, Lec, Pan, O, AV, EPP		Continuous	1 mo. to 1 yr. later		150 for 1st. mo. to 450 for 1 yr.
Surgical Pathology for Specialty Board Candidates	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	S Lim 5	IC	Lab, Clin C, Lec, O, EPP	38 wk.	Arranged	2 or 4 wk. later	C; 6, 12, 18, or 24 days	150 to 250
Surgical Pathology	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	G Lim 9	IC	Lab, Clin C, Sem, Lec, O, EPP	48	Arranged	2 wk. later	C; 12 days	150
Surgical Pathology	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	G Lim 9	IC	Lab, Clin C, Sem, O, EPP	96	Arranged	4 wk. later	C; 24 days	250
Clinical Traineeship in Pathology	University of Kansas Medical Center 39th and Rainbow Blvd., Kansas City, Ks.	G Lim 1	PT	Lab, Clin C, Sem, Lec, O, AV, EPP		Arranged		Arranged	50 mo. Kansas residents; 100 mo. non-residents
Neuropathology	Postgraduate Committee, University of Maryland School of Medicine 522 W. Lombard St., Baltimore	S Lim 3	IC	Lab, Sem	Unknown	Arranged	6 mo. later	C; 6 mo.	210
Pathology of Obstetrics and Gynecology	Harvard Medical School 25 Shattuck St., Boston	S Lim 12	II	Lab, Lec	80	1/ 7/60	5/19/60	I; 20 sessions 4 hr. each	200
Pathology with Clinical Application	University of Michigan Medical School Department of Postgraduate Medicine University Hospital, Ann Arbor, Mich.	S Lim 10	IC or PT	Lab, PD, Clin C, Lec, O, AV	310	9/28/59	12/19/59	C; 60 days	250
Pathology GM 1—Surgical Pathology	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Columbia-Presbyterian Medical Center, New York 32	G	PT	Lab, PD, Clin C, EPP		1st day ea. mo. to July 1960		6 or 12 mo.	300 for 6 mo; 600 for 12 mo.
Pathology PM 31—Surgical	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital, New York 29	B Lim 12	II	Lab, Lec, O, AV	30	9/12/59	12/19/59	I; 15 sessions 2 hr. weekly, Saturdays	100
Pathology PM 30—General and Special Pathology	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital, New York 29	G	II	Lab, Lec, O, AV	30	9/19/59	12/26/59	I; 15 sessions 2 hr. weekly, Saturdays	100
al Pathology	Columbia University College of Physicians	S Lim 12	II	Lab, PD, Lec, O, AV	16	1/ 4/60	1/28/60	I; 8 sessions 2 hr. twice weekly Mondays,	100

Otolaryngology PM 2—Histopathology of the Ear, Nose and Throat	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32 course at Columbia-Presbyterian Medical Center, New York 32	S	II	Lab, Lec, AV, EPP	32	4/ 5/60	5/28/60	I; 16 sessions 2 hr. twice weekly, Tuesdays, Thursdays	100
Special Pathology—Gynecological and Surgical Pathology	New York Medical College Flower and Fifth Ave. Hospitals Fifth Ave., and 106th St., New York	S Lim 9	II	Lab, Lec, O, AV	90	Arranged		I; 30 sessions 3 hr. twice weekly, Tuesdays, Fridays	200
Gynecological and Obstetrical Pathology	New York Polyclinic Hospital 345 W. 50th St., New York 19	S Lim 8	IC	Lab, PD, LC, Clin C, Lec	15	Arranged		C; 10 days	50
Urological Pathology	New York Polyclinic Hospital 345 W. 50th St., New York 19	S Lim 8	IC	Lab, PD, Clin C, Lec	15	Arranged		C; 10 days	50
Surgical Pathology	New York Polyclinic Hospital 345 W. 50th St., New York 19	G Lim 10	IC	Lab, PD, LC, BR, Clin C, Lec	50	4/ 1/60 10/ 1/60	4/30/60	C; 24 days	50
532—Toxicology	New York University Post-Graduate Medical School 550 First Ave., New York 16	G and non-physicians Lim 6	IC	Lab, Sem, Lec, AV, EPP		Arranged		Arranged	100 per mo.
Gynecological Pathology—Correlation of Pathologic Findings with Clinical Diagnosis	University of Texas Postgraduate School of Medicine 1400 Outer Belt Drive, Houston 25, Tex. course at University of Texas M. D. Anderson Hospital and Tumor Institute, Houston, Tex.	B Lim 4	II	Lab, Lec	8	9/ 1/59 10/ 6/59 11/ 3/59 12/ 1/59	9/24/59	I; 8 sessions 1 hr. twice weekly, Tuesdays, Thursdays	10
Pathologic Anatomy and Pathology of Human Tumors	University of Texas Postgraduate School of Medicine 1400 Outer Belt Drive, Houston 25, Tex. course at University of Texas M. D. Anderson Hospital and Tumor Institute, Houston, Tex.	G and residents	II	Lec	26	10/ 7/59	3/30/60	I; 26 sessions 1 hr. weekly, Wednesdays	30
General Oncology	University of Texas Postgraduate School of Medicine 1400 Outer Belt Drive, Houston 25, Tex. course at University of Texas M. D. Anderson Hospital and Tumor Institute, Houston, Tex.	G	II	Lec	12	11/25/59	2/10/60	I; 12 sessions 1 hr. weekly, Wednesdays	25
Dermatopathology	University of Texas Postgraduate School of Medicine 1400 Outer Belt Drive, Houston 25, Tex. course at University of Texas M. D. Anderson Hospital and Tumor Institute, Houston, Tex.	G and residents Lim 20	II	Lec, AV	17	3/ 1/60	6/21/60	I; 17 sessions 1 hr. weekly, Tuesdays	30

PEDIATRICS

(See also Allergy, Neurology, Surgery, Psychiatry)

Clinical Traineeship and Special Skills Course—Pediatrics	College of Medical Evangelists 1720 Brooklyn Ave., Los Angeles 33	G	PT	PT	Arranged	Arranged	2 weeks later	Full time	Unknown
Fever	Department of Continuing Medical Education in Medicine and Health Sciences University of California Medical Center Second and Parnassus Ave., San Francisco course at Children's Hospital, San Francisco	G Lim 100	IC	Lec, Pan, O, AV	7	3/19/60	3/19/60	C; 1 day	12.50
Clinical and Research Advances in Pediatrics and Child Guidance Problems	University of Colorado School of Medicine 1200 E. Ninth Ave., Denver 20 course at Stanley Hotel, Estes Park, Colorado	S Lim 200	IC	Sem, Lec, Pan, O, AV	36	9/ 3/59	9/ 8/59	C; 4½ days	60; or 35 for each part
Pediatric Postgraduate Day	University of Colorado School of Medicine 1200 E. Ninth Ave., Denver 20	B	II	PD, LC, Sem, Lec, Pan, O, AV	36	10/ 2/59	5/ 6/60	I; 9 sessions 4 hr. first Friday each month	Nil
13th Connecticut Postgraduate Seminar in Psychiatry and Neurology—Pediatric Neurology	Program Director, Connecticut Postgraduate Seminar in Psychiatry and Neurology Connecticut State Hospital, Middletown, Conn.; course at Yale University School of Medicine, New Haven, Conn.	S	II	Lec, O	16	2/15/60	4/ 4/60	I; 2 hr. weekly	Nil

Title of Course	Location	Designed For	Type	Methods of Education	Total Hours	Starting Date	Ending Date	Time Arrangement	Fee
Radiology PM 31—Chest	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital New York 29	B	IC	Lec, AV, O	10½	9/28/59	10/ 6/59	C; 7 days	50
Radiology PM 80—Roentgenographic Interpretation of Diseases of the Bones and Joints	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Hospital for Joint Diseases New York 35	S	II	Lec, O, AV	24	9/30/59	12/10/59	I; 12 sessions 2 hr. weekly, Wednesdays	150
Radiology PM 30—Differential Diagnosis in Gastrointestinal Radiology	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital New York 29	G Lim 3	II	PD, LC, Sem	10	10/13/59 3/29/60	12/15/59	I; 10 sessions 1 hr. weekly, Tuesdays	50
Radiology PM 34—Chest, Differential Diagnosis in Radiology of the Chest	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital New York 29	G Lim 3	II	PD, LC, Sem	15	10/19/59 3/14/60	12/21/59	I; 10 sessions 1½ hr. weekly, Mondays	50
Radiology PM 1—Radiological Physics	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Columbia-Presbyterian Medical Center, New York 32	S	II	Lec, O, AV	36	1/ 5/60	5/ 5/60	I; 36 sessions 1 hr. twice weekly, Tuesdays, Thursdays	50
Radiology PM 32—Roentgen Diagnosis of Lesions of the Gastrointestinal Tract, Gall Bladder, and Pancreas	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital New York 29	G	IC	Lec, O, AV	10½	3/14/60	3/22/60	C; 7 days	50
Radiology PM 2—Neuro-Radiology	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Columbia-Presbyterian Medical Center, New York 32	S	IC	PD, Lec, Pan, O, AV	37½	4/11/60	4/15/60	C; 5 days	100
Radiology PM 33—Radium Therapy	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital New York 29	S	II	Lec, O, AV	12	5/17/60	6/21/60	I; 6 sessions 2 hr. weekly, Tuesdays	50
Radiology PM 52—Megavoltage Therapy	Columbia University College of Physicians and Surgeons 630 W. 168th St., New York 32; course at Mount Sinai Hospital New York 29	S	II	Lec, O, AV	12	5/19/60	6/23/60	I; 6 sessions 2 hr. weekly, Thursdays	[illegible]
Roentgen Diagnosis in Gastroenterology	Joint Committee on Post-Graduate Education 1313 Bedford Ave., Brooklyn, N. Y.; course at Beth-El Hospital, Brooklyn, N. Y.	G Lim 20	II	Lec, O	8	10/59	12/59	I; 8 sessions 1 hr. weekly, Tuesdays	20
Diagnostic Roentgenology in Desired Field	New York Medical College Flower and Fifth Ave. Hospitals Fifth Ave., and 106th St., New York	G	PT	Lab, PD, LC, BR, Clin C, Sem, Lec, Pan, O, EPP		Arranged		4-6 weeks arranged	150 for 4 wks.; 250 for 6 wks.
Radiation Physics and Protection—Principles of Physics, X-ray Production, Measurement	New York Medical College Flower and Fifth Ave. Hospitals Fifth Ave., and 106th St., New York	G	PT	Lab, PD, LC, Clin C, Sem, Lec, Pan, O, EPP		Arranged		4-6 weeks arranged	150 for 4 wks.; 250 for 6 wks.
Radium and Roentgen Therapy—Individualized	New York Medical College Flower and Fifth Ave. Hospitals Fifth Ave., and 106th St., New York	G	PT	PD, LC, BR, Clin C, Sem, Surg, Lec, Pan, O		Arranged		4-6 weeks arranged	150 for 4 wks.; 250 for 6 wks.
Practical Roentgenological Interpretation	New York Polyclinic Hospital 345 W. 50th St., New York 19	G Lim 12	IC	PD, LC, Lec	180	4/ 1/60 10/ 1/60	6/30/60	C; 72 days	300
653—Clinical Radiation Therapy	New York University Post-Graduate Medical School 550 First Ave., New York 16	G Lim 2	II	PD, LC, BR, Clin C, Sem, Lec, O	54	9/20/59	1/27/60	I; 18 sessions 3 hr. weekly, Wednesdays	100
651—Diagnostic Radiology for General Practitioners	New York University Post-Graduate Medical School 550 First Ave., New York 16	G Lim 50	II	Lec	60	9/23/59	4/27/60	I; 30 sessions 2 hr. weekly, Wednesdays	125
1812—Introduction to Radiological Health	New York University Post-Graduate Medical School 550 First Ave., New York 16	G and non-physicians Lim 35	IC	Lab, Lec, AV	70	10/12/59	10/23/59	C; 10 days	100
1812-L—Radiological Health Laboratory	New York University Post-Graduate Medical School 550 First Ave., New York 16	G and non-physicians Lim 10	IC	Lab, Lec, AV	70	10/26/59	11/ 6/59	C; 10 days	100

652—Radiobiology	New York University Post-Graduate Medical School 550 First Ave., New York 16	G Lim 20	II	Sem, *Lec*	34	2/ 3/60	5/25/60	I: 17 sessions 2 hr. weekly, Wednesdays	Unknown
4813—Radiation Hygiene *Measurements*	New York University *Post-Graduate* Medical School 550 First Ave., New York 16	G Lim 16	IC	Lab, Lec, AV	140	4/18/60	5/13/60	C; 20 days	200
General Roentgenology	Goldwater Memorial Hospital Welfare Island, New York	B Lim 3	PT	Lab, PD, LC, BR, Clin C, Sem, Lec, Pan, O, EPP		Arranged	1 yr. later	5½ days weekly	Unknown
X-Ray Protection	*Chief, Radiological Health Training Activities;* Division of Radiological Health, U. S. Public Health Service; Robert A. Taft Sanitary Engineering Center 4676 Columbia Pkwy., Cincinnati 26	S Lim 30	IC	Lab, Lec, O, AV, EPP	30	10/26/59	10/30/59	C; 5 days	Nil
Medical Aspects of *Radiological* Health (50R)—Biological Effects of Radiation, Safe *Practices* with Radionuclides and X-rays.	Robert A. Taft Sanitary Engineering Center 4676 Columbia Pkwy., Cincinnati 26	G Lim 28	IC	Lab, Lec, Pan, O, AV, EPP	70	11/30/59	12/11/59	C; 10 days	Nil
Advanced Radiotherapy—Instruction *and* Demonstration of Low, Medium and Supervoltage Radiotherapy, Curietherapy and Their Application to Cancer	*University of Puerto Rico,* Puerto Rico Nuclear Center, Mayaguez, P. R.: course at *Dr. I. Gonzalez Martinez* Oncologic Hospital, San Juan, P. R.	S		PD, LC, BR, Clin C, Sem, Lec, O		Arranged	At least 30 days later		25
Practical Course in *Radiological* Physics	University of Texas Postgraduate School of Medicine 1400 Outer Belt Drive, Houston 25, Tex.; course at University of Texas M. D. Anderson Hospital and Tumor Institute, Houston, Tex.	S *and residents* Lim 6	IC	Lab, Sem, Lec, EPP	160	2/ 1/60	3/25/60	C; 40 days	200

SURGERY

(See also Anatomy, Cardiovascular Disease, Peripheral Vascular Disease)

Clinical Traineeship and Special *Skills Course—Surgery*	College of Medical Evangelists 1720 Brooklyn Ave., Los Angeles 33	G	PT	PT	Arranged	Arranged	2 weeks later	Full time	Unknown
A Series of Postgraduate Surgical Clinics and Symposia	U.S. Veterans Administration Hospital (Fort Miley) 42nd Ave. and Clement St., San Francisco	G Lim 300	II	Lab, PD, LC, Sem, Lec, Pan, O	12	9/22/59	11/ 3/59	I: 6 sessions 2 hr. weekly, Tuesdays	15 AAGP members; 20 non-members; no fee interns and residents
Surgical and Orthopedic Aspects of Trauma	Department of the Army Office of the Surgeon General Education and Training Division Washington 25, D.C.; course at Brooke Army Hospital, Brooke Army Medical Center, Fort Sam Houston, Tex.	B Lim 100	IC	PD, BR, Clin C, Sem, Lec, Pan, O	35	3/14/60	3/18/60	C; 5 days	Nil
Surgery in Acute Trauma	Department of the Army Office of the Surgeon General Education and Training *Division* Washington 25, D.C.; course at Fitzsimons Army Hospital, Denver	G Lim 100	IC	Sem, Lec, Pan, O	24	4/ 4/60	4/ 6/60	C; 3 days	Nil
Symposium on Current Surgical Practices	Department of the Army Office of the Surgeon General Personnel and Training Division Washington 25, D.C.; course at Walter Reed Army Institute of Research, Washington 12, D.C.	S (Military personnel only) Lim 75	IC	PD, Clin C, Sem, Lec, O TV	20	4/18/60	4/20/60	C; 3 days	Nil
Seminar in Surgery—Recent Advances	University of Florida College of Medicine Gainesville, Fla.	B	IC	PD, Clin C, Sem, Lec, Pan, O	15	1/14/60	1/16/60	C; 2½ days	25
Trauma	Emory University School of *Medicine* 69 Butler St., S.E., Atlanta 3, Ga.	S	IC	Unknown	40	10/26/59	10/30/59	C; 5 days	Unknown
Course I—Surgical Technic in General Surgery	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	G Lim 20	IC	Lab, PD, LC, BR, Surg, Lec, O, AV, EPP	90	9/21/59 10/19/59 11/30/59 Once each mo. during 1960	10/ 2/59	C; 11 days	250
Surgery of Colon and Rectum	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	S Lim 18	IC	Lab, PD, LC, BR, Surg, Lec, O, AV	35	9/21/59 10/26/59 11/30/59 2/22/60 4/ 4/60 5/ 2/60 6/ 6/60	9/25/59	C; 5 days	125
General Surgery—Board Review Part I	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	S Lim 10	IC	Lab, PD, LC, BR, Surg, Lec, O, EPP	110	10/ 5/59	10/17/59	C; 12 days	300

MEDICAL NEWS

ILLINOIS

Chicago

Postdoctoral Study in Statistics.—Awards for study in statistics by persons whose primary field is not statistics but one of the physical, biological, or social sciences to which statistics can be applied are offered by the department of statistics of the University of Chicago. The awards range from $3,600 to $5,000 on a 9 months' basis or $4,400 to $6,000 on an 11 months' basis. The closing date for application for the academic year 1960-1961 is Feb. 15, 1960. Information may be obtained from the Department of Statistics, Eckhart Hall, University of Chicago, Chicago 37.

Society News.—The following officers were elected to the Chicago Orthopaedic Society for the year 1959-1960; president, Dr. Newton C. Mead; vice-president, Dr. Carroll B. Larson; president-elect, Dr. Sidney Sideman; secretary, Dr. Jerome G. Finder; and treasurer, Dr. Ralph T. Lidge.——The Chicago Society of Industrial Medicine and Surgery elected the following officers: president, Dr. George J. Cooper; vice-president, Dr. Richard E. Heller; secretary, Dr. Bille B. Hennan; and treasurer, Dr. Charles M. Drueck.

Personal.—Dr. Nels M. Strandjord, assistant professor, department of radiology, University of Chicago, was appointed a James Picker Foundation scholar. Announcement of the appointment was made in Washington, D. C., by the National Academy of Sciences–National Research Council on behalf of the foundation. The appointment carries with it a grant of $4,000 to support Dr. Strandjord in his teaching duties and in his research on x-ray diagnosis of stomach cancers.——Dr. Loyal Davis, chairman, department of surgery, Northwestern University Medical School, received an honorary fellowship in the Royal College of Surgeons of Edinburgh, Scotland, July 23 at a convocation held during a meeting of the Canadian and British Medical associations in Edinburgh. Dr. Davis, the only surgeon from the United States to be so honored, received the honorary fellowship of the Royal College of Surgeons of England in 1955.

Prosthetic Education Program.—Northwestern University Medical School announced the launching of its prosthetic education program, reportedly the first facility of its kind in the Midwest. The official opening of the new program was marked by a reception July 30 in the Rehabilitation Institute of Chicago, where the school is located. The new school will operate on a training grant from the Department of Health, Education, and Welfare, Office of Vocational Rehabilitation. This is Northwestern's second government project in the prosthetics field. The first was the Prosthetic Research Center, established in 1956 by the Veterans Administration for developing new prosthetic devices and fitting techniques. The combined annual budgets of the two projects total $150,000. Courses in the new school will disseminate contemporary information about the prescription, fabrication, and fitting of artificial limbs and braces and the rehabilitation of the orthopedically handicapped. Twenty-one courses lasting from one to three weeks each will be offered during the academic year to physicians, prosthetists, therapists, and rehabilitation counselors. Directly responsible for the organization of the new program is its academic adviser, Dr. Clinton L. Compere, associate professor in orthopedic surgery at Northwestern. The program's director is J. Warren Perry, Ph.D., assistant professor of neurology and psychiatry.

NEW JERSEY

Meeting of Clinical Researchers.—On Sept. 16, the New Jersey Chapter of the American Federation for Clinical Research will meet at the Veterans Administration Hospital, East Orange. There will be a joint meeting with the section on experimental medicine and surgery, Academy of Medicine of New Jersey. Four papers are scheduled as follows:

The Pathophysiology of Dumping Syndrome, Dr. Bernard H. Chaiken, Short Hills.
The Medicolegal Aspects of Medical Research, Dr. William Furst, East Orange, president, New Jersey Neuropsychiatric Association.
T. P. I. in Related Tests, Dr. George H. Kostant, New York City.
The Effect of Smoking on Pulmonary Function, Dr. Edwin L. Rothfeld, Newark.

Each paper will be discussed following its presentation. Dr. Robert M. Pocelinko, Newark, is the secretary of the New Jersey chapter and Dr. Victor Parsonnet, Newark, is president.

Blood Bank in East Orange.—Ground will be broken in East Orange on Saturday, Sept. 12, for the Ballantine Memorial Essex County Blood Bank building, Dr. Kenneth E. Gardner, Bloomfield, president of the blood bank, announced. A $250,000 contribu-

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

tion for the land and building, at Grove Street and Sussex Avenue, was given by P. Ballantine & Sons as a memorial to employes of Newark who gave their lives in service in World War II. This fund was set aside some years ago to be used as a memorial. The bank was organized in 1947, and there were 1,457 donors during the first year. The 1958 donor total was 17,170. The nine chapters of the American Red Cross recruit blood donors from the 22 Essex municipalities as well as from Kearny, Harrison, and Arlington. The 26 hospitals in the area use a total of about 30,000 units of blood a year, with more than half of this amount being provided through the Essex County Blood Bank.

NEW YORK

Symposium on Cinefluorography.—The second annual Symposium on Cinefluorography will be held Nov. 13 and 14, at the University of Rochester Medical Center. This symposium will emphasize the clinical and investigative value of cineangiocardiography; in addition, time will be provided for the presentation of information on image intensifier equipment, photographic technique and apparatus, and papers dealing with other clinical uses of cinefluorography. The program will begin with the "Second Annual Lecture on Cinefluorography of the University of Rochester School of Medicine and Dentistry," by Dr. Frank L. Campeti, who will summarize six years of clinical and experimental work on cineangiocardiography, and will review the indications and limitations of the method. Following this, a cardiologic team will discuss the diagnosis, prognosis, and surgical treatment of congenital and acquired heart disease. On Nov. 13, a panel of radiologists will extend this discussion to radiologic diagnosis. Cinefluorograms demonstrating will be shown that evening. The morning of Nov. 14 will be devoted to cinefluorographic equipment; motion-picture technique, including editing, print control, and special effects; cinefluorographic installations; and miscellaneous equipment, such as recording devices and injection apparatus. Saturday afternoon is reserved for the presentation of submitted papers dealing with previously unpublished information. Presentation of these papers will be limited to 20 minutes plus an additional 10 minutes for discussion. The deadline for the descriptions of cinefluorograms and abstracts of papers is Sept. 1. For information write Dr. George H. Ramsey, Chairman, Department of Radiology, University of Rochester School of Medicine and Dentistry, 260 Crittenden Blvd., Rochester, N. Y.

New York City

Fellowships in Endocrinology and Metabolism.—The availability of junior or senior fellowships in endocrinology and metabolism in the department of medicine, Cornell University Medical College, has been announced. These fellowships are to be designated the Ephraim Shorr Fellowships in Endocrinology in memory of Dr. Shorr, who for many years headed this section at Cornell. The fellows will be under the supervision of Dr. Ralph Peterson, associate professor of medicine. Stipends will be between $5,000 and $7,500 per year, depending on the number of years following graduation and the number of dependents. The deadline for applications is Oct. 15. Applicants should write for information to Dr. E. Hugh Luckey, Chairman, Department of Medicine, Cornell University Medical College, 1300 York Ave., New York 21.

Dr. Day to Go to Pittsburgh.—Dr. Richard L. Day, professor of pediatrics, State University of New York Downstate Medical Center, Brooklyn, was appointed medical director of Children's Hospital of Pittsburgh and chairman of the department of pediatrics at the University of Pittsburgh School of Medicine. Dr. Day will go to Pittsburgh in early 1960. He succeeds Dr. Edmund R. McCluskey, who resigned the two positions last year to become vice-chancellor for Pitt's Schools of the Health Professions. Dr. George H. Fetterman will continue to serve as acting medical director of Children's Hospital until Dr. Day arrives. Dr. Wayne H. Borges, associate professor of pediatrics will continue as acting chairman of the department of pediatrics until Dr. Day arrives. Dr. Day has been professor of pediatrics at Brooklyn since 1953.

Dr. Snyder Named College President.—Dr. Ralph E. Snyder, dean of New York Medical College, was elected president of the institution by the board of trustees. Dr. Snyder was appointed dean in 1953 and has functioned as chief executive officer of the institution since 1957. He will continue to hold the title of dean in addition to that of president. New York Medical College was founded in 1860, with William Cullen Bryant as its first president, and will celebrate its centennial with a year-long series of academic events beginning in the fall. As president of the college, Dr. Snyder is also head of Flower and Fifth Avenue Hospitals. He is also head of the New York Medical College–Metropolitan Hospital Center, the city's newest medical center composed of the college, Flower and Fifth Avenue Hospitals, Metropolitan Hospital, and Bird S. Coler Hospital.

NORTH CAROLINA

Annual Heart Symposium.—On Oct. 9, the 10th annual Winston-Salem Heart Symposium will be held at the Hotel Robert E. Lee. A panel discussion, "The Impact of Acute Metabolic Disorders on the Cardiovascular System," will be held in the morning, moderated by Dr. Philip A. Tumulty, Baltimore. Following the panel the following papers will be presented:

Practical Clues in the Interpretation of the Electrocardiogram, Dr. Marion Bryant, New York City.
Chronic Anti-Coagulant Therapy in Strokes and Heart Disease, Dr. Irving S. Wright, New York City.
Long-Range Management of Rheumatic Fever and Systemic Lupus, Dr. Tumulty.
Repair of Aneurysms—When and How?, Dr. Oscar Creech Jr., New Orleans.

A clinical pathological conference will be held at 4 p. m. A banquet is planned for 7 p. m. For information write the Forsyth Heart Society, Inc., 236 Nissen Building, Winston-Salem, N. C.

OHIO

Gift for Building and Endowment.—A 20-million-dollar gift from the Leonard C. Hanna Jr. Fund to Western Reserve University's School of Medicine and University Hospitals of Cleveland will be used for building and endowment purposes, according to officials of the two institutions. Each institution will receive 10 million dollars. Fund trustees said the gift was in recognition of the joint development program of the medical school and the hospitals. Chairman of the University Medical Center Development Committee is Mr. George M. Humphrey, former U. S. secretary of the treasury. Under his leadership the group hopes to raise 40 million dollars in the next 10 years to expand the joint facilities of the School of Medicine and University Hospitals. University President John S. Millis said that about 7 million of the 10-million-dollar gift designated for Reserve would go into the endowment fund to increase medical faculty salaries. The balance will go with matching federal funds to modernize the present medical school building and to erect an additional five-story structure. According to Dr. Millis, $1,300,000 of the matching federal funds have been received. Stanley A. Ferguson, director of University Hospitals, said that the 10 million dollars coming to his organization would be used for buildings and equipment. On Aug. 12, 1941, Leonard C. Hanna Jr. incorporated the Hanna Fund. He served as president of the board of trustees until his death in October, 1957. The group changed its name to the Leonard C. Hanna Jr. Fund earlier this year.

PENNSYLVANIA

Philadelphia

Lectures on Nutrition and Metabolism.—The Home for the Jewish Aged, in cooperation with the Committee on Nutrition and Metabolism, Philadelphia County Medical Society, and the National Vitamin Foundation, is sponsoring a series of lectures on nutrition and metabolism as they relate to specific medical problems of the aged, as follows:

Oct. 11—Dr. Robert W. Hillman, Brooklyn, "The Geriatric Patient—Nutritional Requirements."
Nov. 11—Dr. Herbert Pollack, New York City, "General Therapeutic Nutrition with Emphasis on Obesity."
Dec. 9—Dr. Richard W. Vilter, Cincinnati, "The Relation of Nutrition to Cardiovascular Disease."

PUERTO RICO

Dr. Vivas Named Dean.—Dr. Joseph R. Vivas was named dean of the University of Puerto Rico School of Medicine, San Juan, thus filling the vacancy created by the resignation of Dr. E. Harold Hinman on June 6. Dr. Hinman has accepted a position with the Public Health Division of the International Cooperation Administration. A 1934 graduate of the Medical College of Virginia, Dr. Vivas was director of graduate education at the Walter Reed Hospital in Washington from 1953 to 1957 and since that time has been chief of medicine and director of Gorgas Hospital in the Canal Zone.

TENNESSEE

Plan Medical Center Addition.—A three-story building providing expanded facilities for both radiological research and patient treatment will be the next addition to Memphis Medical Center. Dr. David S. Carroll, head, department of radiology, University of Tennessee College of Medicine and the City of Memphis Hospitals, said a portion of the space devoted to basic radiological research will permit the addition of personnel to the staff to expand the research program. The new building will be erected in the rear of the John Gaston Hospital. According to preliminary plans the new structure will connect to the Gaston Hospital and the out-patient clinic to the Gailor Hospital Building. The building, to be constructed and equipped at a cost of $1,500,000, will add 34,000 square feet to the Medical Center. The City of Memphis Hospitals is providing one million dollars, the University of Tennessee, $255,000, and the National Institutes of Health of the U. S. Public Health Service, $145,000.

WISCONSIN

Dr. Jacoby Named Anesthesia Head.—Dr. Jacob J. Jacoby, director of anesthesia, Ohio State University, Columbus, accepted an appointment at Marquette University School of Medicine, Milwaukee, as professor and head of the division of anesthesiology. The appointment was effective Aug. 1. Dr. Jacoby will be a full-time anesthesiologist at the Medical School and the Milwaukee County Hospital. His duties will be concerned with establishing a training program in anesthesiology for medical students and residents at Milwaukee County Hospital. By July, 1960, at least eight residencies in anesthesia will be available. Dr. Jacoby will also help to expand the already existing anesthesia program at the Veterans Administration Hospital, Wood, where he will serve as a consultant in anesthesia.

GENERAL

Meeting on Electrodiagnosis.—The sixth annual scientific session of the American Association of Electromyography and Electrodiagnosis will be held in Rochester, Minn., on Saturday and Sunday, Aug. 29 and 30. Those who wish additional information should write to Dr. Edward H. Lambert, Mayo Clinic, Rochester, Minn., Program Chairman.

Research Grants and Fellowships.—The National Institutes of Health, Public Health Service research center at Bethesda, Md., reported that 181 research grants and 232 fellowships totaling $4,471,475 were awarded during June. Of the month's total, $2,619,830 was allocated to support 288 new research grants and fellowship awards. The remaining $1,851,645 was for the continuation of 60 previously approved research grants totaling $1,450,766, and the continuation of 65 fellowships totaling $400,879. The new research grants were made to 89 institutions in 28 states, the District of Columbia, and 6 foreign countries. The new fellowships were awarded to 163 U. S. scientists and 4 scientists from other countries for study in 78 institutions in 29 states, the District of Columbia, and 6 foreign countries. Through the recently activated international postdoctoral fellowship program, the four fellowships were provided to investigators from Switzerland, Chile, Colombia, and the Netherlands.

Fellowships for Pediatric Residencies.—The recipients of the 1959 Wyeth Laboratories pediatric residency fellowships were announced by Dr. Philip S. Barba, Philadelphia, past-president of the American Academy of Pediatrics and chairman of the fellowship selection committee. The pediatric program, sponsored by the Wyeth Fund for Postgraduate Medical Education, provides a grant of $4,800 to each physician, thus enabling him to spend two years of advanced study in the care and the treatment of children. The 20 recipients, from 16 different states, are the second group to benefit from the program established last year by the Philadelphia pharmaceutical manufacturing firm. Selection was made on the basis of "interest in pediatrics, character, able performance of duties, and academic competence." The Wyeth fellowship winners may attend any hospital whose residency is accredited by the Residency Review Committee of the American Board of Pediatrics and the Council on Medical Education and Hospitals of the American Medical Association.

Northwest Proctologic Meeting.—The third annual meeting of the Northwest Proctologic Society will be held Aug. 27-29, at Timberline Lodge, Mount Hood, Ore. Two panel discussions are planned: "Urologic-Proctologic-Gynecologic Problems" and "Medical Management of Ulcerative Colitis," moderated by Drs. Lawrence Leslie, Eugene, Ore., and George Long, Portland, Ore. The program includes the following papers:

Cryptitis—A Study on Organisms Found, Dr. Howard K. Belnap, Ogden, Utah.
Coccygodynia, Dr. Guy E. Owen, Moscow, Idaho.
The Inoperable Fistula-in-Ano, Dr. E. D. Parkinson, Boise, Idaho.
The Large Long Bowel, Dr. Donald Laird, Portland, Ore.
A Technic for Marking the Mucosa of the Gastro-Intestinal Tract after Polypectomy, Dr. J. P. Sauntry, Seattle.
Use of Hypnosis in Proctology, Dr. Leslie.
Medical Management of Ulcerative Colitis, Dr. Long.

A general discussion, "The Irritable Bowel Syndrome," will be held the morning of Aug. 28. On Aug. 27, anorectal procedures are scheduled to be done at the Multnomah County Hospital, Portland. A banquet is planned for 7 p. m., Aug. 28. For information write Dr. John L. McKay, 645 Medical & Dental Building, Seattle 1.

Institute for Medical Society Management.—A practical "bread and butter" session on medical society organization, operation, and management, the 1959 Institute for Medical Society Management will be held at the Ambassador West Hotel, Chicago, on Wednesday, Aug. 19. The one-day program was designed primarily for presidents, presidents-elect, secretaries, executive-secretaries, and chairmen of policy boards of medical societies. Mr. Thomas A. Hendricks, Chicago, president, Medical Society Executives Association, will open the meeting to be followed by an address by Dr. Ernest B. Howard, Assistant Executive Vice-President, American Medical Association. Panel discussions will be held in six sections beginning at 11 a. m. At the 12:30 luncheon, Dr. Leonard W. Larson, Bismarck, N. D., chairman, Board of Trustees, American Medical Association, will present, "You, Leadership, and American Medicine." From 3:30 to 5 p. m., eight round-table discussions designed to discuss specific problems and exchange ideas and information will be held. The institute will precede the A. M. A.'s Public Relations Institute, Aug. 20-21. For information, write Mr. C. Lincoln Williston, Executive Secretary, Texas Medical Association, 1801 N. Lamar Blvd., Austin, Texas.

Group to Study Trichomoniasis.—Following the symposium on human trichomoniasis held at Rheims in May, 1957, a conference of international representatives was called under the chairmanship of Dr. Gaston Chappaz. This resulted in the formation of an international group to maintain interest and to pursue further studies in this field. The group has been constituted as a permanent commission under the auspices of the International Union Against the Venereal Diseases and the Treponematoses, with headquarters at Institut Alfred Fournier, Paris. The objectives of the study group are as follows: (1) To set-up an international registry of research workers especially interested in the field of human trichomoniasis. (2) To promote international scientific meetings. The first Canadian symposium on Nongonococcal Urethritis and Human Trichomoniasis will be held at Montreal, Sept. 21-22 (Secretary, Dr. Z. Gallai, 8580 Esplanade, Montreal 11, Canada). (3) To aid in the publication of original articles or their abstracts in the various foreign journals. (4) To assist the various research workers in contacting the many public and private organizations for grants. All research workers and other persons interested in this field are invited to become members of this organization by sending a curriculum vitae to Group International D'Etudes de la Trichomonase Humaine, Institut Alfred Fournier, 25 Boulevard St-Jacques, Paris XIV°, France.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Industrial Accidents.—Statisticians of the Metropolitan Life Insurance Company reported that gains in industrial safety have decreased the relative frequency of disabling work injuries in the United States by more than a third in 15 years. Last year's frequency rate for disabling injuries, as reported by the Bureau of Labor Statistics, was the lowest on record—29.4 per 1,000 workers, as contrasted with 45.7 per 1,000 in 1943. Accidents arising out of and in the course of employment in 1958 took 13,300 lives, while 75,000 persons suffered permanent physical impairment and more than 1,700,000 were disabled for at least one day after the day of injury. Industries vary greatly with respect to their work-injury experience, the statisticians point out. The logging industry had as many as 62.3 disabling injuries per million employee hours worked in 1957, and a moderately high ratio of deaths to injuries—nine deaths per 1,000 disabling injuries. The coal-mining industry had a lower frequency rate for injuries than in logging, but the proportion of fatal injuries was three times as great. Other industries with comparatively high frequency and mortality ratios are highway and street construction, other heavy construction, metal and nonmetal mining, and structural steel erection and ornamental iron work. The electric light and power industry, with only 5.5 disabling injuries per million employee hours worked, experienced 29 deaths per 1,000 disabling injuries in 1957—the highest ratio of deaths to injuries of any industry for which data are available. A low frequency and a comparatively high proportion of deaths to injuries is also found for workers in petroleum refining, in steel mills, and in the industrial organic chemical industry.

Yugoslavian Receives Rehabilitation Fellowship.—The World Rehabilitation Fund announced the creation of the Donald Dabelstein Memorial Fellowship and the awarding of the fellowship to Prof. Branko P. Bajić, of Yugoslavia. The fellowship was created to honor the late Mr. Donald H. Dabelstein, former assistant director for program, Office of Vocational Rehabilitation, Department of Health, Education and Welfare, who died Oct. 8, 1958. Announcement of the awarding of the fellowship to Professor Bajić was made simultaneously in Belgrade and New York. Professor Bajić is inspector of special schools in the Republic of Serbia and is head of the section for special education in the Serbian Pedagogic Society. Professor Bajić will begin his year's advanced training in special education for handicapped children in New York City in September. During the period of his fellowship he will also represent Yugoslavia at the eighth World Congress of the International Society for the Welfare of Cripples in New York City Aug. 29-Sept. 3, 1960. The World Rehabilitation Fund, Inc, is a nonprofit organization supported by American industry, foundations, and individuals to assist in the international development of rehabilitation services for the physically handicapped. Currently there are 71 trainees (57 physicians and 14 nonphysicians) from 35 different nations who receive long-term advanced training in the U. S. under the auspices of the fund. Its honorary chairman include Mr. Herbert Hoover, Mr. Harry S. Truman, and Mr. Bernard M. Baruch. Currently the World Rehabilitation Fund is providing fellowships for advanced study in the United States for three other Yugoslavians: Dr. Bosko Zotovic, Dr. Dobrosav Matijasevic, and Mr. Josep Karic, an occupational therapist.

Increase in Hospital Admissions.—Hospitals in the United States cared for 700,000 more cases last year than in 1957, the American Hospital Association reported. A total of 23,697,000 hospital admissions was reported in 1958 as compared with 22,993,000 in 1957. The information was compiled from questionnaires received from 6,786 hospitals in the continental United States. Births reported by the hospitals reached an all-time high of 3,742,000 babies born in 1958. Each day last year there were more than 1,300,000 patients and 48,000 newborn babies in hospitals. The hospitals reported total expenses of $7,133,493,000, of which $4,660,191,000 was for payroll. Total assets for all hospitals amounted to $15,470,017,000. The hospitals employed 1,464,829 personnel in 1958, an average of 111 personnel per 100 patients in voluntary short-term hospitals to 34 per 100 patients in nonfederal psychiatric hospitals. The voluntary short-term hospitals cared for 15,825,136 cases; the average patient stay in these hospitals was 7.4 days. An average of $29.24 a day was spent by these hospitals for the care of each patient, an increase of $2.43 over 1957. Patients in voluntary short-term hospitals paid an average of $1.28 a day less than it cost to care for them. Total income from patients in these voluntary hospitals in 1958 was $3,277,242,000, while expenses were $3,426,520,000. Patient income made up 92.6% of the total income of all these hospitals in 1958, as compared with 91.2% in 1957. The balance came from contributions, grants, and income from such sources as endowments. The average expenditure per day in 1958 for each patient in the nation's federal psychiatric hospitals was $10.61. In the voluntary psychiatric hospitals the average expense per patient day was $16.35; in the proprietary psychiatric hospitals, $17.66; and in the state and local governmental psychiatric hospitals, $4.11. More than 277,000 professional nurses worked full-time in hospitals in 1958. This included over 236,000 nurses as hospital employes and more than 41,000 private duty nurses. Almost 65,000 professional nurses served in hospitals on a part-time basis. More than half of all U. S. hospitals were voluntary hospitals operated not for profit by churches and nonprofit associations. Fifteen per cent were proprietary and 33% were operated by agencies of federal, state, or local government. The federal hospitals represented a little more than 6% of all hospitals. Short-term hospitals cared for 96% of the total admissions while long-term hospitals received 4%. However, 63% of the patients in hospitals each day were in the long-term hospitals.

LATIN AMERICA

Symposium on Atherosclerosis and Coronary Disease.—To celebrate the 15th anniversary of the foundation of the National Institute of Cardiology of Mexico, an International Symposium on Atherosclerosis and Coronary Disease will be held Sept. 20-24, at the institute. The opening ceremony will be attended by the Constitutional President of the United States of Mexico, Adolfo Lopez Mateos. The program includes the following round-table discussions: Epidemiology and Nomenclature; Physiology; Metabolism and Biochemistry; Electrovectorcardiography; New Contributions to Medical and Surgical Therapy; Coagulation and Thrombosis; Clinical Aspects (Etiology and Methods of Diagnosis). All communications will be simultaneously translated into Spanish, French, and English. Registration fee is $100 in Mexican currency. For information write the Instituto Nacional de Cardiologia de Mexico, Ave. Cuauhtemoc 300, Mexico 7, D. F., Mexico.

FOREIGN

International Cytology Conference.—An International Cancer Cytology Conference, sponsored by the Institute de Oncologia and the Ministry of Health, Madrid, Spain, the International Union Against Cancer, and the Pan American Cancer Cytology Society, will be held in Madrid Sept. 22-26, 1960. President of the conference is Dr. J. Sanz Ibañez, director of the Madrid National Cancer Institute, and vice-presidents are Dr. James E. Ayre, Miami; Dr. Edmund V. Cowdry, St. Louis; and Dr. J. H. Maisin, Louvain, Belgium. Dr. Angel Valle Jimenez has been appointed secretary general and Dr. Hubert deWatteville, of Geneva, Switzerland, is general program chairman. Represented on the advisory council are Austria, Belgium, Canada, Denmark, England, Germany, France, India, Israel, Italy, Russia, Sweden, Turkey, and the U. S. The conference will focus on cytology research and advanced methods of cancer control through early cytology diagnosis. A brochure is available for distribution to medical and scientific groups. For information write Miss Elizabeth L. Hughes, U. S. Corresponding Secretary, 3007 Salzedo, Coral Gables, Fla.

Space Medicine Congress in Rome.—The second World and fourth European Aviation and Space Medicine Congress will be held in Rome Oct. 27-31. The following subjects will be developed: (1) present methods and data for the psychosphysic selection of the flying personnel and previsions for the future: (2) occupational pathology of flying personnel, maintenance and improvement of its psychophysic efficiency; (3) advances in scientific research of space medicine. A proposal will be made for the foundation of a European Aeromedical and Space Medicine Association. Persons concerned with aviation and space medicine are invited to participate with scientific papers, preferably relating to the subjects of the meeting. A summary, not exceeding 250 words (in English or French) containing the results and conclusion of researches, and completed by the title, should be sent before Aug. 31 to: "Organizing Committee of Aviation and Space Medicine Congress, 2/A via Piero Gobetti-Rome."

Conference on Medical Education.—In the item "Second World Conference on Medical Education" (Aug. 1, page 1697) under Medical News the dates of the conference should have been Aug. 30-Sept. 4.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Written.* Various locations, July 8, 1960. Final date for filing application is January 8. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications was July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. *Final date for filing application* was May 1. *Oral.* For candidates on the West Coast, Portland, Ore., Sept. 9-12. Final date for filing application was March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application was March 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. New Haven, Nov. 14-16. Sec., Dr. Donald D. Matson, 300 Longwood Ave., Boston, Mass.

American Board of Obstetrics and Gynecology: Applications for certificates, new and reopened, Part I, and requests for re-examination Part II are now being accepted. *Part I. Written.* Jan. 15, 1960. All candidates are urged to make such application at the earliest possible date. Deadline date for receipt of applications is August 1, 1959. No applications can be accepted after that date. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

American Board of Ophthalmology: *Oral.* St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. *Oral.* 1960, San Francisco, May; Chicago, October. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago. Jan. 19-21, 1960. The deadline for the receipt of application is Aug. 15, 1959. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application was April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: New Orleans, Nov. 12-14. Final date for filing application is October 1. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pathology: *Examination in Forensic Pathology.* New Orleans, Nov. 13. Final date for filing application is October 1. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Oral.* Chicago, Oct. 9-11. *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports is July 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application was March 15. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: Chicago, Oct. 19-20; New York, Dec. 14-15; San Francisco, Mar. 14-15, 1960. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Examination.* Washington, Dec. 6-9. Deadline for filing application is July 1. Candidates examined in Diagnostic Roentgenology may expect to be examined in Physics. Obligatory examination in Nuclear Medicine has been postponed until after June 30, 1962 for those candidates being examined in Radiology or Therapeutic Radiology. Until that time the examination in Nuclear Medicine will be optional for those who wish to be examined in Radiology or Therapeutic Radiology. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Candidates are urged to apply several months before completion of training requirements although the closing date for filing applications is August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. *Oral examinations (Part II):* Chicago, Sept. 14-15; Seattle, Sept. 17-18; Baltimore, Oct. 19-20; Cincinnati, Nov. 9-10; Boston, Dec. 14-15; Winston-Salem, No. Car., Jan. 18-19; New York, N. Y., Feb. 15-16; New Orleans, Mar. 14-15; Kansas City, Kans., May 16-17, and Los Angeles, May 19-20. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 1959. Final date for filing application was July 1. *Oral.* September. Final date for filing application was July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: *Written.* Approximately 25 cities throughout the country, December 4, 1959. *Oral-Clinical* and *Examination in Pathology.* Chicago, February 1960. Final date for filing application is Sept. 1, 1959. Sec., Dr. William Niles Wishard, 30 Westwood Rd., Minneapolis 26, Minn.

GOVERNMENT SERVICES

ARMY

Personal.—Col. John H. Voegtly, M. C., was named executive officer to the Army surgeon general in Washington, D. C., replacing Col. Bryan C. T. Fenton, M. C., who was assigned as commanding officer, Martin Army Hospital, Fort Benning, Ga.

PUBLIC HEALTH SERVICE

Natural Fluoride Content of Water.—A new report entitled "Natural Fluoride Content of Communal Water Supplies in the United States," Public Health Service publication no. 655, may be obtained from the U. S. Government Printing Office, Washington 25, D. C. The water supplies of 1,903 cities and towns with a combined population of 7 million contain enough fluoride naturally to prevent most dental cavities. Communities in 43 states use water in which the decay-preventing fluoride occurs naturally. The fluoride found naturally in water is identical in its effect to the fluoride used in controlled fluoridation. The 1,800 cities now adding fluoride to the public water supply adjust the concentration to that found in many of the naturally fluoridated water supplies throughout the country, a concentration of 0.7 to 1.2 parts of fluoride per million parts of water.

Poliomyelitis Vaccine.—The World Health Conference on live poliovirus vaccine held in June at Georgetown University under the sponsorship of the Pan American Health Organization brought together a mass of data about the use of the live vaccine in many areas of the world, including Latin America, Africa, Poland, Czechoslovakia, Russia, Singapore, the Netherlands, and Great Britain. Great progress is being made with these attenuated vaccines, bringing closer to reality the possibility of a safe and effective vaccine of this type. The trials undertaken to date and which have involved large numbers of persons were made mostly in the developing nations. Children in these countries, unlike those in the United States and in other more developed nations, normally develop immunity at an early age because of the widespread occurrence of the poliovirus.

Accordingly, there is need for controlled studies in which, prior to inoculation, persons can be tested for antibody levels, immunized, retested, and the results evaluated on a scientific basis. Mass programs of immunization have provided encouraging but not as yet complete scientific data on which to base a real judgment as to the effectiveness of these live vaccines. To the degree that these mass immunization programs have possibly prevented poliomyelitis in nations where they have been used, the effort has been worthwhile. The Public Health Service will continue to follow the present studies and encourage others with interest and the hope that the result will be a vaccine that is easier to administer, one which may provide longer lasting immunity, and one which, presumably, could be produced at lower cost. To date, the Public Health Service has received no applications for licensing an attenuated virus vaccine. Should such an application be received, its division of biologic standards will exercise its responsibility for insuring that the product is safe, potent, and capable of commercial production.

Disability Days.—As a result of illness and injury, workers with family incomes under $2,000 a year lost an average of 10.3 days from work during the 12 months ending June 30, 1958, as compared with a loss of 5.9 days for those in families earning $7,000 and over. An inverse relationship existed also between income and other forms of restricted activity, such as days in bed due to illness and injury. Workers 65 years of age and over lost about 11 days from work compared with 8.4 days for those in the 45-to-64-year group and 6.3 days for those aged 17 to 44. City children lost 9 days from school, rural nonfarm children 7.8 days, and farm children 7.3 days, on the average, as a result of illness and injury. Farm children 15 and 16 years of age lost about 10 days from school as compared to 6.5 days lost by urban children of these ages.

This information appears in the latest of a series of published statistical reports issued by the U. S. National Health Survey. The data apply to the total civilian population of the country, exclusive of persons confined to long-term institutions. Respiratory illnesses as a group were the leading cause of restricted activity. They were responsible for 40% of all such restriction and 50% of all days in bed. The totals for this group of diseases were affected by the Asian influenza epidemic, but even in a normal year the respiratory diseases are likely to head the list. Circulatory diseases, including heart disease, ranked second in terms of total volume of disability, followed by injuries and their chronic effects, with digestive diseases running a close fourth.

The new publication contains additional statistics on the relationships between disability and various characteristics of the population. The data are derived from the continuing nationwide household interviewing with a representative sample of the population, conducted for the Public Health Service by the U. S. Bureau of Census. The report entitled "Disability Days, United States, July 1957-June 1958" (Public Health Service publication no. 584-B 10) is available from the Superintendent of Documents, Government Printing Office, Washington 25, D. C., at 40 cents a copy.

of Physicians in 1954; member of the American Society of Biological Chemists, American Academy of Arts and Sciences, National Academy of Sciences, and the Société de Pediatrie de Paris; served as a member of the staff and head of the metabolism division of the Children's Hospital; held honorary degrees from Yale University, University of Zurich, and the University of Chicago; editor of the *American Journal of Clinical Investigation* from 1941 to 1947; died in the Massachusetts General Hospital May 28, aged 75.

Glackman, John Clay Ⓜ Rochester, Ind.; Chicago Homeopathic Medical College, 1904; served as chairman of the state board of health; veteran of World Wars I and II; city health officer and member of the city board of health; at one time health officer of Spencer County; died in St. Joseph's Hospital, Kokomo, May 21, aged 78.

Glinert, Mark, Brooklyn; Medizinische Fakultät, der Universität, Vienna, Austria, 1924; died in Bay Harbor, Fla., Feb. 3, aged 62.

Grosjean, Joseph C. Ⓜ Bay City, Mich.; Trinity Medical College, Toronto, Ont., Canada, 1900; past-president of the Bay County Medical Society; for many years vice-president of the Agricultural Life Insurance Company, of which he was medical director; on the honorary staff at Mercy Hospital, where he was a senior surgeon for many years; died May 14, aged 85.

Hajworonsky, George Juri, Cherokee, Iowa; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1947; interned at Columbus Hospital in New York City, where he served a residency; served a residency at St. Francis Sanatorium for Cardiac Children in Roslyn, N. Y., and State Mental Health Institute in Cherokee; died in Iowa City May 19, aged 39.

Harper, Sage Ⓜ Douglas, Ga.; Medical College of Georgia, Augusta, 1933; veteran of World War II; member of the American Academy of General Practice; died in the Douglas–Coffee County Hospital May 26, aged 51.

Hays, William Clarence, Sherman, Miss.; Memphis (Tenn.) Hospital Medical College, 1912; died in Shands Hospital, New Albany, May 16, aged 77.

Hines, John Allen, Alabaster, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1921; served as a member of the county board of education; died in the Highland Baptist Hospital in Birmingham May 22, aged 62.

Holloway, Hosah Sellers Jr. Ⓜ Notasulga, Ala.; Tulane University School of Medicine, New Orleans, 1941; interned at the Charity Hospital in New Orleans; veteran of World War II; died March 14, aged 43.

Howard, Frank Davis, Birmingham, Ala.; University of Tennessee College of Medicine, Memphis, 1948; veteran of World War II; later served in the U. S. Air Force; interned at Jefferson Hillman Hospital in Birmingham, where he served a residency; served a residency at the Lloyd Noland Hospital in Fairfield and the Veterans Administration Hospital in Birmingham, where he was head urologist; died in Tarpon Springs, Fla., May 27, aged 34.

Hubbard, Ralph Waldo Ⓜ Oklahoma City, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1932; veteran of World War II; captured by the Japanese and held a prisoner of war for 32 months; released March 29, 1945; continued service in the Army reserve, retiring with the rank of lieutenant colonel; upon retirement was awarded the Distinguished Service Cross; associated with the Hubbard Hospital, where he died May 19, aged 51.

Hudson, Frederick Auld Ⓜ Enid, Okla.; Northwestern University Medical School, Chicago, 1908; in 1920 president of the Garfield County Medical Society; founder of the Enid General Hospital; died May 17, aged 74.

Humphrey, Henry Martin Ⓜ Kirksville, Mo.; Barnes Medical College, St. Louis, 1899; died May 16, aged 84.

Ironside, Paul Allan Ⓜ Haddonfield, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1930; served on the staff of the West Jersey Hospital in Camden; died in London, England, May 21, aged 57.

Jackson, Greenleaf L., Nashville, Tenn.; Meharry Medical College, Nashville, Tenn., 1911; died in the Davidson County Hospital March 19, aged 69.

Johnston, Louis Campbell Ⓜ Chicago; Northwestern University School of Medicine, Chicago, 1911; fellow of the American College of Surgeons; served during World War I and was awarded the Silver Star for gallantry in action; on the staff of the Grant Hospital; died June 1, aged 71.

Jolley, James Frank Ⓜ Mexico, Mo.; Rush Medical College, Chicago, 1913; fellow of the American College of Surgeons; on the staff of the Audrain Hospital; died May 24, aged 71.

Kaminski, Karolina, Syracuse, N. Y.; Uniwersytet Jana Kazimierza Wydzial Lekarski, Lwów (Lemberg), Poland, 1927; served as senior psychiatrist for the Newark (N. Y.) State School; died April 9, aged 59.

Kinnard, George Potts, Newnan, Ga.; Jefferson Medical College of Philadelphia, 1922; veteran of World Wars I and II; died in the Newnan Hospital March 4, aged 59.

DEATHS

Buck, Ulysses Grant Ⓜ Rothville, Mo.; Keokuk (Iowa) Medical College, 1896; served as president of the school board; associated with the St. Francis Hospital in Marceline, where he died May 3, aged 92.

Fenlon, Robert Laurence Ⓜ Boulder City, Nevada; State University of Iowa College of Medicine, Iowa City, 1919; member of the staff of the Boulder City Hospital; died in Battle Mountain May 19, aged 72.

Fisher, Alfred Taylor, Brooklyn; Medico-Chirurgical College of Philadelphia, 1901; died March 27, aged 79.

Fisher, E. Moore Ⓜ Washington, D. C.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1904; fellow of the American College of Physicians and the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology; consultant in neuropsychiatry, Board of Veterans Appeals, Veterans Administration; died in the Baker Memorial division, Massachusetts General Hospital in Boston May 31, aged 83.

Flanagan, George Ernest Ⓜ Myerstown, Pa.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1923; member of the American Academy of General Practice; veteran of the Royal Canadian Air Force; secretary of the Lebanon County Medical Society; a director of the Myerstown Bank & Trust Company; associated with the Good Samaritan Hospital in Lebanon; died May 24, aged 61.

Foster, L. Fernald Ⓜ Detroit; born in Phillipsburg, N. J., Oct. 10, 1891; University of Pennsylvania School of Medicine, Philadelphia, 1918; secretary of the Michigan State Medical Society for 23 years; in 1954 the society honored him for his many years of outstanding service to the society and to the medical profession; at one time chairman of the board of directors of the Cooperative Medical Advertising Bureau of the American Medical Association; in 1955 vice-president and since 1956 president of the Michigan Medical Service and was named medical administrator of the organization in 1957; a founder of Blue Shield and a member of the board of directors since 1939; served as secretary of the Bay County Medical Society, of which he was past-president; past-president of the Northwest Regional Conference; helped found the Michigan Heart Association and served as its vice-president and first secretary; started the Michigan rheumatic fever control program as a member of the board of directors of the Michigan Society for Crippled Children and Adults; helped found the National Conference on Medical Service and was its first president; veteran of World War I; specialist certified by the American Board of Pediatrics; certified by the National Board of Medical Examiners; member of the American Academy of Pediatrics; formerly practiced in Bay City, Mich., where he was on the staffs of the Bay City General and Mercy hospitals; on the courtesy staff of the Harper Hospital, where he died May 27, aged 67.

Fry, Harvey Murrell, Binghamton, N. Y.; Jefferson Medical College of Philadelphia, 1896; past-president of the Susquehanna County (Pa.) Medical Society; for many years practiced in Rush, Pa.; died in the Binghamton City Hospital May 22, aged 88.

Fuller, William Theophilus, Nashville, Tenn.; Meharry Medical College, Nashville, 1930; also a dentist; died in the Hubbard Hospital May 24, aged 71.

Fuqua, William Arthur Ⓜ Grandfield, Okla.; Medical Department of Tulane University of Louisiana, New Orleans, 1910; medical director and owner of the Grandfield Hospital; died in Wichita Falls, Texas, May 19, aged 79.

Gage, Arthur Tenney, Oxnard, Calif.; Tufts College Medical School, Boston, 1906; associated with the Redlands (Calif.) Community Hospital; past-president of the Redlands Rotary Club; died in the General Hospital, Ventura County, May 16, aged 75.

Gamble, James Lawder Ⓜ Boston; born in Millersburg, Ky., July 18, 1883; Harvard Medical School, Boston, 1910; since 1950 emeritus professor of pediatrics at his alma mater, where he was assistant professor of pediatrics from 1922 to 1929 and professor from 1929 to 1950; instructor of pediatrics at the Johns Hopkins University School of Medicine in Baltimore from 1915 to 1922; served as physician with the American Red Cross in France from 1917 to 1919; in 1955 received the John Howland Medal and Award from the American Pediatric Society, of which he was past-president; member of the American Academy of Pediatrics and in 1946 received its Borden Award; in 1950 received the Chapin Award of the Rhode Island Medical Society and in 1951 the Kober Award of the Association of American Physicians, of which he was a member; received the Moxon Award from the Royal College

---

Ⓜ Indicates Member of the American Medical Association.

of Physicians in 1954; member of the American Society of Biological Chemists, American Academy of Arts and Sciences, National Academy of Sciences, and the Société de Pediatrie de Paris; served as a member of the staff and head of the metabolism division of the Children's Hospital; held honorary degrees from Yale University, University of Zurich, and the University of Chicago; editor of the *American Journal of Clinical Investigation* from 1941 to 1947; died in the Massachusetts General Hospital May 28, aged 75.

Glackman, John Clay Ⓜ Rochester, Ind.; Chicago Homeopathic Medical College, 1904; served as chairman of the state board of health; veteran of World Wars I and II; city health officer and member of the city board of health; at one time health officer of Spencer County; died in St. Joseph's Hospital, Kokomo, May 21, aged 78.

Glinert, Mark, Brooklyn; Medizinische Fakultät, der Universität, Vienna, Austria, 1924; died in Bay Harbor, Fla., Feb. 3, aged 62.

Grosjean, Joseph C. Ⓜ Bay City, Mich.; Trinity Medical College, Toronto, Ont., Canada, 1900; past-president of the Bay County Medical Society; for many years vice-president of the Agricultural Life Insurance Company, of which he was medical director; on the honorary staff at Mercy Hospital, where he was a senior surgeon for many years; died May 14, aged 85.

Hajworonsky, George Juri, Cherokee, Iowa; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1947; interned at Columbus Hospital in New York City, where he served a residency; served a residency at St. Francis Sanatorium for Cardiac Children in Roslyn, N. Y., and State Mental Health Institute in Cherokee; died in Iowa City May 19, aged 39.

Harper, Sage Ⓜ Douglas, Ga.; Medical College of Georgia, Augusta, 1933; veteran of World War II; member of the American Academy of General Practice; died in the Douglas–Coffee County Hospital May 26, aged 51.

Hays, William Clarence, Sherman, Miss.; Memphis (Tenn.) Hospital Medical College, 1912; died in Shands Hospital, New Albany, May 16, aged 77.

Hines, John Allen, Alabaster, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1921; served as a member of the county board of education; died in the Highland Baptist Hospital in Birmingham May 22, aged 62.

Holloway, Hosah Sellers Jr. Ⓜ Notasulga, Ala.; Tulane University School of Medicine, New Orleans, 1941; interned at the Charity Hospital in New Orleans; veteran of World War II; died March 14, aged 43.

Howard, Frank Davis, Birmingham, Ala.; University of Tennessee College of Medicine, Memphis, 1948; veteran of World War II; later served in the U. S. Air Force; interned at Jefferson Hillman Hospital in Birmingham, where he served a residency; served a residency at the Lloyd Noland Hospital in Fairfield and the Veterans Administration Hospital in Birmingham, where he was head urologist; died in Tarpon Springs, Fla., May 27, aged 34.

Hubbard, Ralph Waldo Ⓜ Oklahoma City, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1932; veteran of World War II; captured by the Japanese and held a prisoner of war for 32 months; released March 29, 1945; continued service in the Army reserve, retiring with the rank of lieutenant colonel; upon retirement was awarded the Distinguished Service Cross; associated with the Hubbard Hospital, where he died May 19, aged 51.

Hudson, Frederick Auld Ⓜ Enid, Okla.; Northwestern University Medical School, Chicago, 1908; in 1920 president of the Garfield County Medical Society; founder of the Enid General Hospital; died May 17, aged 74.

Humphrey, Henry Martin Ⓜ Kirksville, Mo.; Barnes Medical College, St. Louis, 1899; died May 16, aged 84.

Ironside, Paul Allan Ⓜ Haddonfield, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1930; served on the staff of the West Jersey Hospital in Camden; died in London, England, May 21, aged 57.

Jackson, Greenleaf L., Nashville, Tenn.; Meharry Medical College, Nashville, Tenn., 1911; died in the Davidson County Hospital March 19, aged 69.

Johnston, Louis Campbell Ⓜ Chicago; Northwestern University School of Medicine, Chicago, 1911; fellow of the American College of Surgeons; served during World War I and was awarded the Silver Star for gallantry in action; on the staff of the Grant Hospital; died June 1, aged 71.

Jolley, James Frank Ⓜ Mexico, Mo.; Rush Medical College, Chicago, 1913; fellow of the American College of Surgeons; on the staff of the Audrain Hospital; died May 24, aged 71.

Kaminski, Karolina, Syracuse, N. Y.; Uniwersytet Jana Kazimierza Wydzial Lekarski, Lwów (Lemberg), Poland, 1927; served as senior psychiatrist for the Newark (N. Y.) State School; died April 9, aged 59.

Kinnard, George Potts, Newnan, Ga.; Jefferson Medical College of Philadelphia, 1922; veteran of World Wars I and II; died in the Newnan Hospital March 4, aged 59.

Kirk, Clair Bishop Ⓢ Mill Hall, Pa.; Jefferson Medical College of Philadelphia, 1908; associated with Lock Haven (Pa.) Hospital; died May 22, aged 75.

Kitchens, Herschell Monroe Ⓢ Waldo, Ark.; University of Tennessee College of Medicine, Memphis, 1914; died May 18, aged 72.

Knipe, William Hugh Wellington Ⓢ Katonah, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1903; specialist certified by the American Board of Obstetrics and Gynecology; life fellow of the New York Obstetrical Society; fellow of the American College of Surgeons; served in France during World War I; formerly on the faculty of the New York Post-Graduate Medical School and Hospital and the New York Polyclinic Medical School and Hospital in New York City, where he was associated with the Gouverneur Hospital; died May 28, aged 78.

Langs, Louis Ⓢ Brooklyn; University and Bellevue Hospital Medical College, New York City, 1915; associated with Adelphi and Brooklyn Doctors hospitals; veteran of World War I; died in the Maimonides Hospital April 18, aged 66.

Liles, Lester McKesson Ⓢ Watsonville, Calif.; Western Reserve University Medical Department, Cleveland, 1898; a member of the city board of health; died in the Watsonville Community Hospital May 18, aged 85.

Lummis, Frederick Rice Ⓢ Houston, Texas; born in Houston Nov. 1, 1884; Jefferson Medical College of Philadelphia, 1913; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; clinical professor of medicine emeritus at Baylor University College of Medicine; past-president of the Harris County Medical Society; in 1945 named chairman of the city board of health; trustee emeritus at Rice Institute; the Frederick R. Lummis Medical Foundation was named for him; consultant, Methodist, St. Luke's Episcopal, Memorial, and St. Joseph's hospitals, and the Hermann Hospital, where he died May 24, aged 74.

MacIntyre, Reginald Walker, New York City; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1907; served on the staff of the New York Polyclinic Medical School and Hospital and Hospital for Special Surgery; died in St. Luke's Hospital May 31, aged 78.

McGovern, Joseph Dunn Ⓢ Wewoka, Okla.; University of Nashville (Tenn.) Medical Department, 1910; on the staff of the Wewoka Memorial Hospital; died May 19, aged 72.

McKean, Alexander C., Harlingen, Texas; Northwestern University Medical School, Chicago, 1903; coroner for the province of Saskatchewan for many years, and was health officer of the town of Rouleau, Sask.; served on the staff of the Providence Hospital in Moose Jaw, Sask.; died April 2, aged 82.

Meisel, Stephen Julian Ⓢ New York City; Schlesische-Friedrich-Wilhelms-Universitat Medizinische Fakultat, Breslau, Prussia, Germany, 1923; associated with St. Clare's Hospital; died in Mount Sinai Hospital May 15, aged 61.

Moffatt, George, Seattle; McGill University Faculty of Medicine, Montreal, Que., Canada, 1902; practiced in Donnybrook, N. D., and later at Crosby, N. D.; died May 26, aged 89.

Morgan, David Wendell Ⓢ Pittsburgh; Albany (N. Y.) Medical College, 1930; fellow of the American College of Surgeons; veteran of World War II; associated with the Western Pennsylvania Hospital; died May 21, aged 58.

Nash, Edwin Alexander Ⓢ Des Moines, Iowa; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1904; author of "Random Rhymes and Poems for Home Folks"; died May 3, aged 84.

Norris, John Franklin, Stewartstown, Pa.; College of Physicians and Surgeons, Baltimore, 1900; veteran of World War I; served as superintendent of the Somerset County Home and Hospital for the Insane in Somerset; formerly on the staff of the State Hospital in St. Peter, Minn.; for many years associated with the Veterans Administration in Camp Custer, Mich., and Sheridan, Wyo.; died in Dallastown May 19, aged 87.

Parrish, Frederick Watson, Tucson, Ariz.; College of Physicians and Surgeons, Los Angeles, 1910; died May 18, aged 89.

Petitt, Percy A., Paola, Kan.; Kansas City (Mo.) Hahnemann Medical College, 1908; county health officer; served on the faculty of the University of Kansas School of Medicine in Kansas City, Kan.; member of the American Academy of General Practice; associated with the Trinity Lutheran Hospital in Kansas City, Mo., where he died May 22, aged 75.

Pinard, Pierre Romeo, Sioux Falls, S. D.; St. Louis College of Physicians and Surgeons, 1893; also a pharmacist; served as vice-president of the Charles Mix County Board of Health; died May 22, aged 89.

Raymond, Edwin Ⓢ Mount Vernon, N. Y.; Universität Bern Medizinische Fakultät, Switzerland, 1938; associated with Mount Vernon Hospital and the Cross County Hospital; died May 8, aged 51.

Robert, Harold Russell, Farmingdale, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1912; at one time on the staff of the Dannemora (N. Y.) State Hospital; died in the Veterans Administration Hospital, Northport, May 2, aged 70.

Rosenstiel, Mary L. Ⓜ Freeport, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; associated with Deaconess and St. Francis hospitals; died May 17, aged 79.

Salinko, Stephen S. Ⓜ Milwaukee; Maryland Medical College, Baltimore, 1901; veteran of World War I and the Spanish-American War; died May 19, aged 88.

Saylor, Howard Lee Ⓜ Huron, S. D.; Starling Medical College, Columbus, 1894; fellow of the American College of Surgeons; veteran of World War I; served as president of the Huron Chamber of Commerce and in January, 1952, received its Distinguished Service Medal; died in St. John's Hospital May 8, aged 85.

Schonwald, John De Witt, Oxford, Ohio; Jefferson Medical College of Philadelphia, 1909; past-president of the Ohio College Health Association; served as medical director of Miami University; died in Sarasota, Fla., May 2, aged 72.

Schwartz, Henry Jacques Ⓜ Brooklyn; University and Bellevue Hospital Medical College, New York City, 1915; died March 15, aged 71.

Scott, George Vane, Jersey City, N. J.; College of Physicians and Surgeons, Baltimore, 1912; died in the Jersey City Medical Center May 17, aged 70.

Seligmann, Fred Siegfried, Forest Hills, N. Y.; Hessische Ludwigs-Universitat Medizinische Fakultat, Giessen, Hesse, Germany, 1914; specialist certified by the American Board of Dermatology and Syphilology; associated with New York University-Bellevue Medical Center and New York Skin and Cancer Hospital; died April 2, aged 69.

Shaddix, Arthur C., Beaumont, Texas; Chicago College of Medicine and Surgery, 1913; associated with Baptist Hospital of Southeast Texas and St. Therese Hospital; died May 20, aged 75.

Sharp, Milton Ragsdale, Granger, Texas; University of Texas School of Medicine, Galveston, 1902; past-president of the Williamson County Medical Society; city health officer; died May 21, aged 81.

Simmons, John Wesley Ⓜ Brunswick, Ga.; University of Georgia Medical Department, Augusta, 1905; served as secretary-treasurer of the Georgia Industrial Surgeons Association; past-president of the Alumni Association of the Medical Department of the University of Georgia; on the staff of the Brunswick Hospital; died May 9, aged 79.

Sismondo, Adele Margaret Ⓜ California, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1938; associated with the Charleroi-Monessen Hospital in Charleroi; died May 19, aged 48.

Stead, Jenny English Crozier, Glendale, Calif; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; served as a medical missionary in India, Persia, and Iran; died April 12, aged 83.

Stricker, Frederick David Ⓜ San Rafael, Calif.; Detroit College of Medicine, 1900; served as executive secretary and state health officer of the Oregon State Board of Health; formerly secretary of the Oregon State Medical Society; past-president of the State and Provincial Health Authorities of North America and the Western Branch of the American Public Health Association; practiced in Tucson, Ariz., from 1919 to 1921; veteran of World War I; following his retirement the Oregon Public Health Association awarded him a plaque for outstanding contributions as a health administrator and organizer; died May 26, aged 84.

Sulman, William Richard Ⓜ Hazleton, Pa.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1925; specialist certified by the American Board of Internal Medicine; member of the American College of Cardiology; fellow of the American College of Physicians; associated with Hazleton State Hospital and St. Joseph Hospital, where he died April 24, aged 59.

Thomases, Saul Ⓜ Stratford, Conn.; New York University College of Medicine, New York City, 1939; certified by the National Board of Medical Examiners; served on the staff of the Bridgeport (Conn.) Hospital; died in the Grace-New Haven Hospital in New Haven May 21, aged 53.

Tonkin, Harry Glenville Ⓜ Martinsburg, W. Va.; Baltimore Medical College, 1908; veteran of World War I; twice mayor of Martinsburg; died in Miami, Fla., May 30, aged 78.

Tshernoff, Leon, New York City; American University of Beirut School of Medicine, Syria, 1912; died March 27, aged 71.

Turner, John Wakeman, Greensboro, N. C.; Northwestern University Medical School, Chicago, 1908; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; veteran of World War I; retired from the Veterans Administration Aug. 2, 1950; died May 9, aged 78.

Turque, Irwin Lawrence, Brooklyn; Long Island College Hospital, Brooklyn, 1925; veteran of World War II; associated with the Long Island College Hospital and the Kings County Hospital; died in the Veterans Administration Hospital May 17, aged 58.

Vereker, Martin Francis Ⓜ Hamilton, Ohio; Medical College of Ohio, Cincinnati, 1902; served as a member of the city council and health commissioner of Hamilton; for many years vice-president and a member of the board of the Columbia Building & Loan Association; died in the Mercy Hospital May 4, aged 83.

Wack, Frederic Van Deursen Ⓜ Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1927; veteran of World War II; died May 27, aged 58.

Walson, Charles Moore Ⓜ Brigadier General, M. C., U. S. Army, retired, Washington, D. C.; born in Laurel, Del., Aug. 24, 1883; Jefferson Medical College of Philadelphia, 1906; at one time practiced in St. Louis, where he was on the faculty of St. Louis University School of Medicine, and an assistant to the city health officer; commissioned a first lieutenant in the medical corps of the U. S. Army in 1912, served as a surgeon with American forces in the occupation of Vera Cruz, Mexico, in 1914; during World War I was an assistant to the chief surgeon of the American Expeditionary Forces in France; after the war, was stationed in Germany; from 1922 to 1926, an executive officer and hospital inspector at Walter Reed Hospital; later assistant to the Seventh Corps Area surgeon at Omaha and surgeon at Fort Benjamin Harrison (Ind.) Station Hospital; from 1936 to 1939 chief of the Plans and Building Branch, Office of the Army Surgeon General in Washington; in 1940 Second Corps Area surgeon and in 1942 became surgeon of the First Army; promoted to brigadier general in 1945; in addition to Army assignments, lectured on vital statistics at Creighton University in Omaha, and on tropical medicine at Indiana University School of Medicine in Indianapolis; became administrator of the American Red Cross Blood Program for the Greater New York area upon his retirement from the Army in 1947; held the post until 1951, when he became consultant to the American Red Cross Blood Program in Washington, serving until 1953; in 1948 went to the Far East on a special mission for the Army Surgeon General; fellow of the American College of Surgeons; held the Legion of Merit; died in the Walter Reed Hospital May 14, aged 75.

Walters, Albert Gerald Ⓜ Detroit; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1921; served as diagnostician for the city board of health; died May 10, aged 60.

Warren, Arthur Bradley Ⓜ Hardwick, Vt.; University of Vermont College of Medicine, Burlington, 1912; veteran of World War I; on the staff of the Hardwick Hospital; died May 2, aged 73.

Warrick, Joseph D. Ⓜ Camarillo, Calif.; Chicago College of Medicine and Surgery, 1917; past-president of the Barker County (Kan.) Medical Society; served as health officer of Sharon, Wis.; staff psychiatrist at Camarillo State Hospital; member of the American Psychiatric Association; died in the Medical Arts Center Hospital in New York City May 4, aged 63.

Welsh, Harold James, Geneva, N. Y.; University of Buffalo School of Medicine, 1924; at one time on the faculty of Cornell University Medical College in New York City; served on the staffs of the Western State Sanatorium in Greenwood Mountain, Maine, and St. Vincent's Hospital in Erie, Pa.; died in the Geneva (N. Y.) General Hospital May 4, aged 61.

Wiggins, Dallas Bronson, Philadelphia; Temple University School of Medicine, Philadelphia, 1913; served on the staffs of the Mercy-Douglass Hospital and the Jefferson Hospital; died April 27, aged 73.

Williamson, Plummer Bridges, Jackson, Miss.; University of Nashville (Tenn.) Medical Department, 1901; served as health officer of Pearl River County; for many years on the staff of the Mississippi State Hospital in Whitfield; died in the University Hospital May 19, aged 84.

Willie, Edward Henry, Brooklyn; Howard University College of Medicine, Washington, D. C., 1921; died in the Kings County Hospital April 8, aged 74.

Wilson, Thomas, Wynne, Ark.; Memphis (Tenn.) Hospital Medical College, 1913; member of the American Academy of General Practice; past-president and vice-president of the state board of health; past-vice-president of the Arkansas Medical Society; veteran of World War I; associated with the Cross County Hospital, where he died May 7, aged 73.

Woldert, Albert Ⓜ Tyler, Texas; University of Pennsylvania Department of Medicine, Philadelphia, 1893; also a graduate in pharmacy; past-president of the Smith County Medical Society; served as city health officer; honorary member of the staffs of the Medical Center Hospital and Mother Frances Hospital; died May 13, aged 92.

Woods, Clarence Hubert, Long Beach, Calif.; Jefferson Medical College of Philadelphia, 1896; died in Claremont May 27, aged 87.

Wyatt, Wortham Ⓜ Winston-Salem, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1913; veteran of World War I; associated with the City Memorial Hospital, where he died May 3, aged 71.

Wynn, Joseph Henry Ⓜ Naperville, Ill.; Chicago Medical School, 1931; died in Hospital of St. Anthony de Padua in Chicago May 11, aged 59.

Young, Ferrin, Florala, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1909; died May 18, aged 70.

Zaletel, Rudolph Peter Ⓜ Chicago; Universita Karlova Fakulta Lékarská, Praha, Czechoslovakia, 1919; died in the Illinois Central Hospital May 10, aged 69.

FOREIGN LETTERS

AUSTRIA

Anemia Infantum Pseudoleukemica.—At the meeting of the Austrian Society for Pediatrics in Vienna on April 7, H. G. Weippl said that, although it was originally considered to be a separate disease entity, opinions on anemia infantum pseudoleukemica now differ between complete repudiation and recognition of it as a reactive syndrome. The speaker reported cases with typical changes, one of a child with anemia of prematurity (second phase, iron deficiency) and another of a child with alimentary iron deficiency anemia, both patients having hepatosplenomegaly and leukocytosis with an increase in immature cells. All symptoms disappeared with the administration of iron alone, thus showing that all the changes depended on the anemia. The concept of a reactive syndrome thus seems to be justified.

Bronchoscopy.—At the meeting of the Society of Physicians in Vienna on April 10, H. Jenny reported results of a series of 2,550 bronchoscopies. Of 140 patients who were subjected to bronchoscopic examination in 1957 carcinoma was visualized in 103, or 73%, and in 64% the diagnosis of carcinoma was confirmed by exploratory excision. These results were much better than those obtained in earlier years, because of greater experience with the method and improved instruments. A special indication is the suspected specific perforation of lymph nodes, which can be removed by adequate endoscopic suction, particularly in children. With early bronchoscopy excellent results may be obtained and dangerous complications prevented. Endoscopic examinations are also indicated in patients with pulmonary tuberculosis and in those with all types of chronic, unexplained, inflammatory changes in the lungs and air passages. The risk associated with the procedure is slight if it is performed with the aid of general anesthesia, provided a reliable anesthetist is available.

Acid-Base Balance and Peritonitis.—At the same meeting R. Kühlmayer stated that by analysis of the acid-base balance and the electrolyte structure it was established, in 27 patients, that peritonitis is regularly associated with a compensated or manifest metabolic acidosis. The degree of the acidosis depends on the extent, duration, and severity of the peritonitis and makes prognostic conclusions possible. These acidotic disturbances of metabolism may be observed in patients with peritonitis of various origins, and also in those with postoperative or perforation peritonitis associated with ileus. The disturbances of electrolyte structure, which consist in a reduction of the total electrolyte concentration in the plasma, and, therefore, hyponatremia, or occasionally hypopotassemia and hypochloremia, are the result of a loss of electrolytes due to deficient absorption of electrolyte-containing digestive juices from the upper portions of the intestines, as a sequela of intestinal paralysis.

At the second surgical clinic of the University of Vienna the correction of the metabolic acidosis in patients with peritonitis was accomplished with a combination of sodium bicarbonate and sodium lactate. With this compound it was possible to correct the metabolic acidosis within one or two days in patients who had peritonitis which had been controlled surgically, resulting in an improved general condition. The other electrolyte disturbances may be treated according to the usual principles. The prognosis of the surgically controlled peritonitis can be improved specifically by the correction of the metabolic acidosis. Osmotic nephrosis was rarely observed at the autopsy of patients in whom a therapeutic correction of electrolyte disturbances had been attempted.

Circumscribed Opacities in the Lung.—At the same meeting H. Kunz stated that the interpretation of roentgenograms of the lung is not, as a rule, difficult, with the exception of circumscribed opacities. With each such round focus one must first decide whether the process is benign or malignant. In a series of 759 patients who were admitted to the second surgical clinic of the University of Vienna 40 had round foci, and in 6 the condition was inoperable. In many cases valuable time was lost through expectant treatment, because of the erroneous assumption of tuberculoma in patients with a malignant tumor or in those with benign tumors who had been treated for tuberculosis for months or even years.

Fracture of Vertebrae in Patients with Tetanus.—At the meeting of the Austrian Society for Pediatrics in Vienna, on May 5, H. A. Lippert reported that compression fractures (partly multiple) of the middle thoracic vertebrae were observed immediately after the onset of disease in three of eight young patients with tetanus. Fractures of the vertebrae have been observed frequently after tetanus in juvenile patients, and the prognosis is favorable. Roentgenologic examinations should be performed before the patients get out of bed, since the post-tetanic vertebral changes are asymptomatic in most patients, and back pain and in-

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

creased kyphosis may be observed only in severe cases. The speaker emphasized that vertebral fractures have not been reported after treatment of tetanus with muscle relaxants, but that vertebral fractures occurred in two patients with moderately severe tetanus who, according to Mollaret's scheme of treatment, had not been treated with curare. For orthopedic treatment exercises, bed rest, with the patient placed on a hard mattress in the prone position, and a body cast have been used. Roentgenograms of fractures occurring after electroshock therapy are identical with those of fractures occurring after tetanus. The condition must be differentiated from vertebral osteochondrosis and congenital platyspondylisis.

Hydramnios.—At the Meeting of the Society of Physicians in Vienna on May 22, R. Ulm stated that the genesis of the amniotic fluid and the causes of its abnormal increase are not fully understood. With the aid of radioactive isotopes it was found that the infant in utero drinks about 8 liters of amniotic fluid daily which, after absorption by the intestine, is returned to the mother through the placenta. If for any reason the infant is not able to swallow, or if the gastrointestinal passage is interrupted, then the amniotic fluid circulation is disturbed and hydramnios results. Clinical observations on 30,000 deliveries provided complete confirmation of these views. Observation of hydramnios should indicate to the obstetrician the possibility of an intestinal abnormality and the necessity of an immediate pediatric examination of the newborn infant, so that a lifesaving operation may be performed while the infant's condition is still good.

The diagnostic usefulness of reported hydramnios for the early diagnosis of complete occlusion high in the gastrointestinal tract was confirmed by H. G. Wolf. A hydramnios was recorded four times in five patients with duodenal atresia and only once in six patients with duodenal stenosis. Of 4 patients with atresias of the proximal jejunum it was estimated that twice the normal amount of amniotic fluid was present before birth, while in 63 who had occlusion of the distal gastrointestinal tract a hydramnios was observed only once, in a patient with meconium ileus. In 24 patients who had esophageal atresia with a lower esophagotracheal fistula hydramnios was found only once, and this fistula was permeable only with a capillary probe. Since the significance of an early diagnosis of acute abdomen in the newborn infant cannot be overemphasized, hydramnios of the mother that cannot be explained otherwise should be the cause of appropriate examination of the newborn infant.

O. Thalhammer stated that in the surprisingly large water exchange of the fetus the fluid is secreted, at least predominantly, by the prismatic amnion cells of the middle portion of the placenta. It is swallowed by the fetus, reabsorbed by the intestine, and passed on to the fetal heart by way of the mesenteric veins. In the arterial portion of the fetal circulation most of the water is carried back into the amnion by way of the umbilical arteries through the kidneys and urinary passages. This circulation starts with swallowing and renal function at the end of the fourth month. Disturbances anterior to the fetal heart are frequently associated with hydramnios, and the same applies to disturbances between the fetal heart and the circulation of the mother (diabetogenous fetal disease with fetal-placental endarteritis obliterans). Disturbances between the fetal heart and the orifice of the urethra are frequently associated with oligohydramnios. Disturbances anterior to the fetal heart may be due to other causes.

The speaker observed a child who died of congenital ascites on the first day of his life. Autopsy revealed peritonitis with extensive adhesions close to the mesenteric root, which caused congestion, still clearly visible at autopsy, of the veins peripheral to the adhesions. The otherwise healthy mother had observed a great increase in weight and in her circumference in the course of the last weeks of her pregnancy, and she had had hydramnios. Only one part of the obstructions in the mentioned route of the water is associated with hydramnios and with oligohydramnios respectively. There must be still unknown compensatory mechanisms. Only a few cases of hydramnios (3 of the 95 in the speaker's series) could be explained by obstructions in the digestive tract.

Epilepsy in Childhood.—At the meeting of the Society of Pediatricians in Vienna, on April 14, Dr. H. C. Groh stated that he had treated children who had various epileptic manifestations with a series of anticonvulsant drugs. Detailed diagnostic procedures were used to determine the predominant form of convulsion and the course of the disease. Special attention should be given to the frequency with which the attacks occur, the eliciting factors, the possibilities of cerebral injuries, familial factors, and peculiarities in the environment of the child. Primary extracerebral causes of seizures and space-filling intracranial lesions should be excluded. The electroencephalogram is important for the determination of the type of seizure. The selection of the proper drug is determined by the form of seizures, the frequency with which they occur, the hour at which they occur, and the toxicity and cost of the drug. It is not wise to change from one drug to another too soon, because many anticonvulsants become effective only after they have been used for some time. A gradually increasing dose should be used until the maximal effect short of intoxication is achieved.

For infrequent major and focal seizures in infants mephobarbital or phenobarbital was preferred. In those with more frequent seizures of these types, if barbiturates were ineffective, methylphenylethylhydantoin (Epilan), with or without a small dose of barbiturates; a combination of diphenylhydantoin and mephobarbital (Comital); Comital with phenobarbital; Epilan with phenylethylbarbital; or Epilan with phenobarbital was used. For minor seizures phenylchloroacetylurea was given to most patients but in those with a classic spike-and-wave electroencephalogram or those in whom this drug was ineffective trimethadione and paramethadione were used.

For petit mal attacks characterized by momentary loss of consciousness, in patients with classic spike-and-wave paroxysms, these same drugs were given but in older children, especially those who also had major seizures, these drugs were combined with barbiturates or hydantoins. If these combinations were ineffective phenylchloroacetylurea was given, and if this was also ineffective acetazolamine or caffeine was tried. For psychomotor seizures phenylchloroacetylurea or primidone and hydantoins were given. Lightning, nodding, and salaam convulsions presented a therapeutic problem. There was no preferred therapy. Primidone and phenobarbital were the most promising. Trimethadione and paramethadione were ineffective. If a patient had combined seizures the major seizures were treated first, preferably with primidone. Minor seizures were often influenced at the same time. Once the major seizures are under control, combination with other drugs may be of value. Average doses for the various age periods, determined empirically, have been tabulated and were given as a basis for dosage. Regular supervision of treatment is essential. This includes advice by the physician as to living routine, education of the child, and periodic leukocyte counts in order to recognize early allergic or toxic side-effects of the drugs. In patients in whom treatment seems satisfactory yearly electroencephalograms should form the basis for the prognosis. Reduction of the dosage and the final withdrawal of the drug may be considered after freedom from seizures for two or more years.

INDIA

Hyperpyrexia in Children.—Ghosh and Singh (*Indian Journal of Child Health.* vol. 8, April, 1959) treated 11 children who had hyperpyrexia (a temperature of 105 F [40.6 C] or more) and such neurological symptoms as unconsciousness, drowsiness, and convulsions, with a lytic cocktail. Treatment was started with an intramuscular injection of 50 mg. of chlorpromazine, the dose being less in younger children. This was followed immediately by an intravenous drip of 5% dextrose solution at a rate of 15 drops per minute; 1 to 1.5 cc. of a mixture containing 50 mg. of promethazine, 50 mg. of chlorpromazine, and 100 mg. of meperidine in 12 cc. of saline solution was injected into the drip tubing every 15 minutes. Six such injections were given. This was followed by an intravenous drip containing 150 mg. of promethazine, 150 mg. of chlorpromazine, 150 mg. of meperidine, and 200 mg. of thiamine in 900 cc. of 5% dextrose solution. This was allowed to flow at the rate of 15 to 20 drops per minute until the temperature came down to 101 F (38.3 C), when it was replaced by plain 5% dextrose solution. The cocktail was restarted, if there was a secondary rise of temperature, until the temperature again came down to 101 F. The rate of the inflow was increased to 25 or 30 drops per minute if the temperature did not come down quickly enough. Supportive therapy in the form of cortisone intramuscularly or prednisone by mouth was given to five patients, thyroid extract orally to two, and oxygen by a nasal catheter to three.

Specific therapy was started once the general condition after hypothermia improved. This treatment was designed to enable the autonomic nervous system to withstand the stress of hypothermia and thus overcome the risk of circulatory failure, which invariably occurred in the past when patients with hyperpyrexia and neurological involvement were treated only by surface cooling with ice, and when the general condition became worse and terminated in death as the temperature came down. In this series of 11 patients 7 survived. Of these six were normal when last seen and one had a neurological defect in the form of generalized rigidity and inability to speak. The temperature came down in all cases, the fall being dramatic in all but two. Ice packs were used only if the fall in temperature was slow. In those who survived the general condition improved as the temperature came down, restlessness diminished, and response to stimuli returned. None of the patients developed any pulmonary complications.

Tetanus in Children.—Matveyev and Paul (*Indian Journal of Child Health*, vol. 8, April, 1959) found that tetanus accounted for 1.65% of all admissions to the Children's Hospital in Delhi. The incidence of tetanus neonatorum was exceptionally high—38 of 279 newborn infants, or 14%. The highest incidence was in August, September, and October. This may have been due to conditions of temperature and humidity during these months being favorable to the multiplication and growth of Clostridium tetani and, to a certain extent, to the increased birth rate during these months. As infection in these cases usually occurs at birth, when the umbilical cord is cut, the incubation period of tetanus neonatorum was four to seven days. Most of these children came from areas of the city with poor sanitary conditions.

There was often a history of siblings also having suffered from tetanus, and in two families several children had been affected. In 35 of 38 cases of tetanus neonatorum deliveries had been conducted at home by untrained persons, with violation of the most elementary laws of asepsis. None had received antitetanus serum before admission. In the older children meningitis and such local conditions as regional lymphadenitis; peritonsillar, retropharyngeal, and alveolar abscesses; acute parotitis; and severe stomatitis had to be excluded.

Although an incubation period of less than 48 hours usually means an unfavorable prognosis, two children with an incubation period of less than 24 hours survived. There was no correlation between the severity of the disease and the state of nutrition and physical development of the child. Absence of vomiting in these patients was striking, none of the children vomiting even once. Increased perspiration, which is supposed to be characteristic of tetanus, was not observed in any. Of 47 patients 18 had cyanosis. Only two of these survived, and their cyanosis was slight. This is an unfavorable sign; its degree corresponds to the severity of the disease. Trismus was present in 41, opisthotonus in 23, and risus sardonicus in 15. The convulsions were tonic in 30, tonic-clonic in 16, and absent in 1. Cessation of tonic convulsions was a good prognostic sign and was observed from the 8th to the 22nd day of the disease. The umbilicus was normal in only 8 of the 38 who had tetanus neonatorum, the rest showing some evidence of umbilical infection. The principal complications were bronchopneumonia in seven patients and stomatitis, due to moniliasis or secondary infection, in five.

Nasal feeding was used in most patients in the early stage. Oral feeding was started when the general condition improved, usually in the second week. Antitetanus serum was given to all the children, the dose varying from 40,000 to 300,000 I. U. It was given either as a single dose or in a course of injections. The effect of the serum administration was not closely related to the time of its administration after the onset of the disease. Thus, all the 14 children who received it on the first day died; 18 got it on the second day and 2 of these recovered; and 6 got it on the fourth day and 4 recovered. The effect depended more on the severity of the disease and was of help in subacute cases. As anticonvulsant therapy paraldehyde injections, phenobarbital orally, and chloral hydrate rectally were administered in early cases but were found to be unsatisfactory. Injections of paraldehyde and antibiotics were abandoned, since they disturbed the patients. Instead sedatives were given orally or rectally and the broad-spectrum antibiotics orally. Preparations of chlorpromazine and prednisolone were used to increase the sedative and relaxant effect and to combat toxemia and hyperpyrexia. The mortality was very high—34 of the 47 died.

Infantile Scurvy.—Although children of parents in a low income group live on cereals and insignificant amounts of milk, with hardly any supplement of fresh fruits or vegetables, frank scurvy is not so common as would be expected. Manchanda and Gupta (*Indian Journal of Child Health*, vol. 8, April, 1959) analyzed a series of 25 patients aged 7 months to 5 years who had frank scurvy. All were from very poor families. Three were breast fed, 5 received human and cow's milk, 4 got only cow's milk, 11 got a mixed diet, and 2 got cereals only. The diet of the mothers of the breast-fed babies was grossly inadequate during both pregnancy and lactation. All had a history of some illness in the preceding three to four months. Common misdiagnoses included caries of the spine, rheumatic arthritis, acute poliomyelitis, acute osteomyelitis, acute leukemia, paraplegia, and anemia. Sixteen had moderate and nine severe anemia. The characteristic radiologic signs of scurvy were seen more easily in the lower extremities than in the upper. Treatment consisted of 250 mg. of ascorbic acid given intramuscularly twice a day and 60 to 120 cc. of fresh orange juice, for varying periods. Results were good in all patients except one who had hepatic failure and jaundice and who died four days after admission. Improvement was evident in the others three to eight days after starting treatment.

Effects of Alcohol and Nicotine on Hypertension.—Gour and Mital (*Current Medical Practice*, vol. 3, April, 1959) investigated the reasons for advising patients with hypertension to restrict the use of alcohol and nicotine by studying this relationship in four groups of chicks. The first group served as controls. In the second group hypertension was induced by substituting 0.9% sodium chloride solution for drinking water. The third group received 50% alcohol, after hypertension was induced with salt, and the fourth consisted of chicks with salt-induced hypertension who were exposed to tobacco smoke. The normal range of systolic pressure in the control group varied between 112 and 136 mm. Hg and of diastolic between 92 and 116 mm. Hg. The total plasma cholesterol level in this group varied between 102 and 118 mg.% and the plasma lipid phosphorus level between 7.3 and 8.4 mg.%. The ratio of total cholesterol to lipid phosphorus was 14:1. In the second group the maximum level of systolic pressure was 168 mm. Hg and of diastolic 140 mm. Hg. The values for total plasma cholesterol (C), lipid phosphorus (P), and the C:P ratio, however, were unchanged in spite of the raised blood pressure. In the third group the blood pressure was a little lower than in the second group but the other values were unaltered, and there was no evidence of atherosclerosis in any of the chicks when they were killed after 24 weeks of observation. In the fourth group neither the blood pressure nor the blood chemistry was any different from that seen in the second group, and on autopsy no atherosclerotic changes were detected after 24 weeks of study.

Internal Carotid Thrombosis.—Ramamurthi and Rao (*Journal of the Indian Medical Association*, vol. 32, May 1, 1959) stated that thrombosis of the internal carotid artery is a much more common condition than is suspected. Many cases diagnosed as cerebral vascular disease are instead caused by occlusion of carotid arteries. The difficulty in diagnosing this condition is due to the variety of symptoms that may be manifest. The authors observed eight patients with thrombosis of the internal carotid artery, only three of whom showed the classical symptoms of ipsilateral blindness with contralateral hemiplegia. Three of the eight patients had papilledema, two had ocular palsy, three had mental disturbances, and two did not have any weakness of the contralateral limbs. The age of these patients varied between 11 and 55 years. The right side was involved in six cases and the left in two. One patient had a frank frontal lobe syndrome of mental disturbance. Five of these patients were treated with arterectomy, resection of the superior cervical ganglion, and in one ligation of the internal jugular vein, with a view to improving the cerebral blood supply.

Self-sufficiency in Drugs.—India's drug production in 1958 was nearly twice that of 1957. If the present rate of expansion continues India should be self-sufficient by the end of 1961 in the production of most raw materials or basic substances required for the pharmaceutical industry. It is thus expected that importation of drugs will be greatly reduced in the foreseeable future.

Carcinoma of the Uterus.—D. B. Reddy and coworkers (*Journal of the Indian Medical Profession*, vol. 5, March, 1959) found that although the incidence of carcinoma of the body of the uterus is low as compared with other malignant tumors of the genital tract, it has been rising. Of 34 cases observed by them since 1954, 10 were encountered during the last year alone. The average age of the patients in this series was 45 years (range 20 to 70). About 40% were in the age group 20 to 40. All the patients in this series except one were married and had borne one or more children. This does not correspond with the usual belief that cancer of the body of the uterus is more common in the unmarried and nulliparous. Most of the lesions were confined to the endometrium and myometrium. Early diagnosis and surgical treatment are therefore beneficial in these cases.

Leprosy.—At the annual general meeting of the leprosy workers' association the chairman said that the terror of the disease had definitely decreased. Compulsory segregation is fast being abolished, and the leprosy patient is no longer inevitably linked in the public mind with a leprosarium; 72 leprosy centers have been established, covering a population of over 8,500,000 and treating about 100,000 patients.

Birth Weight.—Mukherjee and Biswas (*Journal of the Indian Medical Association*, vol. 32, May 16, 1959) studied 1,054 consecutive births to determine the influence of the period of gestation, the sex of the infant, parity and age of the mother, and the socioeconomic status on the birth weight of the infant. The gestation period was calculated from the first day of the last menstrual period. The duration of pregnancy among the patients studied ranged between 7 and 11 lunar months, and most of the births took place at 39 to 41 weeks, when the average birth weight was 6 to 7 lb. (2,721 to 3,175 Gm.). The average birth weight for the entire series was 5.96 lb. (2,060 Gm.). A progressive increase in the birth weight was noticed, as the gestation period advanced, from a minimum of 2.06 lb. (1,160 Gm.) to a maximum of 6.59 lb. (2,925 Gm.).

The rate of increase was not uniform throughout the range of variation of the gestation period. It increased rapidly with gestation up to 35 weeks, after which it showed a decline. For the shorter periods of gestation male infants were slightly lower in weight than female infants in corresponding periods of gestation, but after 38 weeks they gained more weight than their female counterparts. The average birth weights varied between 5.67 (2,600 Gm.) for the first parity and 6.36 lb. (2,860 Gm.) for the eighth parity. The average birth weight showed a tendency to rise systematically with parity up to the fourth order, but the pattern of variation among higher parities was not systematic. The minimum age of the mother in this study was 14 and the maximum 44 years. Most of the mothers were in the age group 25 to 30. The average birth weight in the 14-to-18-year-old mothers was 5.5 lb. (2,190 Gm.) and in the 21-to-25-year-old mothers was 6.23 lb. (2,835 Gm.). Up to the age of 25 years there was a tendency for the birth weight to increase systematically with the mother's age. At higher ages a reverse tendency was noticed, the birth weight diminishing with advancing age.

Most primiparas were between 18 and 21 years of age. A systematic increase in the birth weight with the mother's age was noticed in the primiparas up to the age of 30 years. Among the group of para 2 and para 3 women a systematic increase in birth weight with the mother's age was seen, up to the age of 25 years, followed by a gradual but consistent decrease with advancing age. The pattern of variation of birth weights with respect to age was more or less the same for different gravidas. The birth weights of babies from higher socioeconomic groups were consistently higher than those coming from a lower class, for all periods of pregnancy. A larger proportion of the poorer mothers had extremely short periods of gestation, which also contributed to the reduction in the average birth weight of their babies to a significant extent.

Tuberculosis Association of India.—Presiding over the 20th annual meeting of the tuberculosis association of India in New Delhi, A. Kaur said that though in a welfare state the main responsibility for health services lay with the government, humanity would be the poorer if men and women had no opportunities to fulfill their desire to help their fellow men. Welfare organizations were therefore in a key position to provide for such aspects of human needs as could not be adequately covered by government agencies. The tuberculosis seal sale campaign has helped to make the public more conscious of the tuberculosis problem, but the campaign has not maintained the steady progress which was anticipated. The situation should be studied to find out how this drive could be intensified and made the real pivot of a whole nation's movement against tuberculosis.

Effect of Drug on Avoidance Response.—Sinha and Acharya (*Indian Practitioner*, vol. 12, March, 1959) stated that tranquilizing drugs such as Rauwolfia alkaloids and chlorpromazine disrupt a well-established conditioned avoidance response, which is not due to disturbance of motor coordination. They studied the blocking effect of reserpine and chlorpromazine and the facilitating effect of methylphenidate and epinephrine on conditioned avoidance responses in rats to find out whether the former decreased and the latter increased the rate of conditioning. The animals were trained during a preliminary period of 10 days so that the avoidance response was fully established. The four drugs were given on different days to groups of animals according to a counterbalanced sequence of drug order to exclude any effect of the drug previously used, and placebos were included to serve as controls.

The drugs were given intraperitoneally, and sufficient time was allowed after administration for the peak effect of the drug to develop. This time was three hours for reserpine, two and one-half hours for chlorpromazine, one and one-half hours for methylphenidate, and one-half hour for epinephrine. The animals were then subjected to the conditioned stimulus. A determination of the specific drug effect on these responses was made on five consecutive days. Reserpine and chlorpromazine definitely depressed and blocked the avoidance responses, while methylphenidate and epinephrine increased them. With placebos the responses were maintained at a constant level. The response developed under one drug could be altered by administering another. All these drugs acted on the conditioned avoidance responses in a specific manner, while leaving the unconditioned responses unaffected. Epinephrine enhanced the response from 65 to 100% and methylphenidate from 40 to 100%. Reserpine blocked the response from 30 to 0% and chlorpromazine from 10 to 0%. With placebos a constant response of 33% was obtained.

A New Antimalarial Drug.—A. P. Ray and co-workers (*Journal of the Indian Medical Association*, vol. 32, May 16, 1959) studied the efficacy of 377-C-54, a naphthalene derivative that has shown a high degree of activity against avian and simian plasmodia, against human malaria under rural and urban conditions in 124 patients (70 with vivax and 54 with falciparum malaria). Thick and thin smears were made for detecting the parasite. At least 100 fields of the thick film were examined before submitting a negative report. Three dosage schedules were tried: (1) 200 mg. twice a day on the first and once a day on the second day, a total of 600 mg.; (2) a single dose of 400 mg.; and (3) a single dose of 600 mg. The first schedule was used in urban hospital patients and the other two in home treatment in rural areas. Blood smears were collected daily to determine the rate of clearance of asexual parasites from the peripheral circulation, which was taken as the main criterion of the activity of the drug. In hospital patients 92.3% of those with vivax malaria became afebrile within 48 hours, while relief of clinical symptoms in all patients could be recorded only after 72 hours.

The response in those with falciparum malaria was not so good; 55.5% became afebrile within 48 hours, 77.7% within 96 hours, and the rest took as long as five days. Parasite clearance was 100% in those with vivax malaria within 48 hours. In those with falciparum malaria it was 55.5% within 48 hours and 100% only after 96 hours. With a single dose of 400 mg. clearance of asexual parasites was 61.1% in those with vivax malaria within 24 hours and 94.4% within 48 hours. It took 72 hours for parasite clearance to occur in 100%. Corresponding figures for those with falciparum malaria were 64.7%, 82.3%, and 96 hours. The response, however, was remarkably prompt with the single dose of 600 mg. In those with vivax malaria parasite clearance was 97.4% within 48 hours. In those with falciparum malaria the rings had disappeared in 67.5% within 24 hours and in 100% within 48 hours. Thus the therapeutic response was variable with different plasmodia. With the divided dosage schedule its action against Plasmodium vivax was comparable to that of chloroquine. The response was much slower against Plasmodium falciparum with this dosage. The drug is therefore unsuitable in divided doses for patients with this type. The response with a single dose of 600 mg. was comparable to that with chloroquine. The drug was on the whole well tolerated.

NETHERLANDS

Influenza Pandemic.—In the *Nederlands tijdschrift voor geneeskunde* (103:1098, 1959), M. F. Polak reported the results of his analytic studies on morbidity and mortality in the Netherlands influenza pandemic of 1957. One-third to one-half of the population was affected. The first cases were observed in the southeast of the country, and within four weeks the whole country was involved. There were 1,230 deaths or 11.2 per 100,000 inhabitants. The areas affected early showed a higher death rate (14.1) than the regions affected later (10.4). This was probably due to the lower morbidity in the areas affected later. The 20-to-29-year-old age group showed the lowest death rate (3.0). With increasing age this rate increased; in the group of those aged 80 and above it was 171.2 per 100,000.

During the epidemic there was a decrease in mortality among younger people and an increase in that among older age-groups. In general, women showed a higher death rate than men up to the age of 40, but above that age the death rate was higher in men. On the average the death rate was lower in large towns (7.7) than in villages (14.5). The reason for this difference is not clear. There was no difference in morbidity between towns and villages.

Of the 1,230 who died 799 had a preexistent disease. The occurrence of such a disease was most frequent among older people, reaching 82% in the group of those aged 70 and above. The intercurrent diseases most often encountered were oligophrenia, multiple sclerosis, paralysis agitans, valvular heart disease, tuberculosis, kyphoscoliosis, and diabetes. In the 20-to-39-year-old age group the mortality among pregnant women was more than twice that among nonpregnant women (8.0 and 3.8 respectively). In addition to the deaths directly due to influenza an approximately equal number of deaths were reported in the same period. These additional deaths were mostly in persons in the highest age groups, who died of respiratory and circulatory diseases. Influenza was probably a contributing factor in these cases.

Pulmonary Changes in Influenza.—After the 1918 influenza pandemic some observers reported certain pulmonary changes which were thought to be the direct result of this disease. Later the relationship between such anatomic changes and the influenza virus could be proved by the presence of antibodies against this type of virus. P. de Baan (*Nederl. tijdschr. geneesk.* 103:721, 1959) studied 10 patients who died of influenza in the 1957 pandemic. The same changes were seen again, although more frequently and to a more pronounced degree. This was thought to be partly the result of the present role of antibiotics, which in many instances prevented secondary infection. The frequent occurrence of these lesions was ascribed to certain pneumotropic properties of the virus involved.

On macroscopic examination the lungs of these patients showed hemorrhagic areas with well-defined lobular limitations. On microscopic examination the main characteristics appeared to be degeneration, necrosis, and desquamation of the epithelial cells at all levels of the bronchial tract. This was followed by a vigorous regeneration which was most pronounced in the terminal bronchioles and in the respiratory bronchioles of the first and second order. In the alveoli the degeneration was accompanied by a hemorrhagic and fibrinous effusion. In the central areas of some alveolar lesions thrombosis of the capillaries was seen. This resulted in complete necrosis within about two weeks. In other areas, however, the capillaries remain open. In such instances signs of regeneration of the alveolar cells were seen. The peculiar character of the changes in the epithelial cells all along the bronchial tract warranted the conclusion that the virus could invade not only the bronchial epithelium but also the most peripheral alveolar cells. The author stressed the relationship between the alveolar effusion and the often severe cyanosis and dyspnea observed in patients suffering from this disease. Furthermore, this explains the high death rate in patients with a preexistent heart disease.

Persons Aged 100 and Above.—According to the central bureau for statistics there appeared to be, on Jan. 1, 1959, 58 persons (22 men and 36 women) who were 100 years old or older (in a population of about 11 million). Of these 27 were exactly 100 years of age and one was 109. Among these persons there were no married couples.

NORWAY

Pathogenic Staphylococci in Hospitals.—Since 1949 Prof. T. M. Vogelsang has been studying the behavior of staphylococci in response to penicillin medication. In his latest report (*Tidsskrift for den norske laegeforening*, May 1, 1959) he stated that tests were made in 1958 to determine whether the use of antibiotics other than penicillin might replace it and thereby reduce the frequency of penicillin-resistant strains. The author concluded that if the examination is made early in an epidemic, it may be possible to show that only one or two persons are carriers of the strain causing the epidemic. If they are patients they must be isolated, and if they are members of the hospital staff they should be temporarily suspended. Since so many persons are intermittent carriers, there is a good chance of the epidemic strain's disappearing from the upper respiratory tract during residence outside the hospital.

Epidemic Hepatitis.—Since infectious hepatitis was added to the list of reportable diseases about 17 years ago, 106,982 cases have been put on record, with an annual fatality of more than 2,000 in recent years. Early in 1956 an outbreak in a rural community 40 miles from Oslo inspired the public health authorities to send Dr. T. Bjerkedal (*Tidsskrift for den norske laegeforening*, May 1, 1959) to study it. He visited 1,042 persons in 273 homes. Of these 156 (15%) gave a history of jaundice at some earlier date. Suspicion fell on a 34-year-old man who, in the autumn of 1955, had infectious hepatitis under conditions peculiarly favorable to its spread to persons whose water supply was downstream of the river to which he had had access. In many cases, however, the disease must have spread by direct contact. The comparative immunity enjoyed during the present outbreak by persons with a record of jaundice at an earlier date suggested that infectious hepatitis often confers a lasting immunity. The author concluded that sanitary control of water supplies could do much to prevent future outbreaks. His optimism was more guarded with regard to the prevention of infection by direct contact, because the disease may be infectious before it has become patent, by virtue of the jaundice it provokes.

Iron in the Marrow.—At the Halden City Hospital Serck-Hanssen and Breck (*Farmakoterapi*, vol. 1, 1959) stained 40 sternal marrow smears from 23 patients having various forms of anemia with potassium ferrocyanide. Their objectives were (1) to discover a simple method for demonstrating stainable iron in sternal marrow, (2) to explore the possibilities of a semiquantitative grouping of the preparations, and (3) to learn whether there is any correlation between the quantity of stainable iron in sternal marrow and the patient's anemia, as estimated by the usual hematological criteria. In their opinion the most important outcome of this test was its ability to demonstrate the absence of stainable iron in a smear. When this is the case, treatment with iron is indicated. In their 23 patients in whom iron was demonstrable in this way iron medication was ineffective. Although no definite upper or lower limit could be put to the iron content of marrow, the quantity of such iron often varies with the hematological picture. Therein lies the diagnostic value of this test.

UNITED KINGDOM

Conan Doyle Centenary.—The centenary of the birth of Conan Doyle (1859-1930), the doctor who created Sherlock Holmes, fell on May 22. He studied medicine at Edinburgh University and after spending six months as a ship surgeon and another six months as an assistant, he settled in general practice at Southsea, where in eight years he never earned more than $1,200 a year. Yet he had a good knowledge of medicine, as in his novels he describes extra systoles, edema due to fibrillation, angina pectoris, aneurysms, rheumatic valvular disease, and left ventricular failure with orthopnea, with careful adherence to medical probabilities. During these eight years he was writing profusely and many of his stories were published, although many were also returned. He never earned more than $200 a year from writing during this period. He left Southsea in 1890 to study ophthalmology in Vienna. On his return he settled in Devonshire Place, London, where most of the Sherlock Holmes stories were written. He soon gave up medicine for writing, although he served as a doctor in the South African war in 1899, and wrote the history of the campaign. In 1902 he was knighted. Conan Doyle continued to write until 1926, when the last of the Sherlock Holmes stories appeared. He died in 1930.

At a Conan Doyle centenary exhibit in London is an original letter from Paul Ehrlich expressing his interest in the writer and asking for a signed portrait. Ehrlich's request was granted and the portrait of Doyle always hung in his study. Other interesting exhibits are the *Strand* magazine with the first of the Sherlock Holmes stories, and an illustrated program of the dramatic version staged in New York in 1900 with William Gillette as Holmes.

Institute of Diseases of Chest.—The existing laboratories of the Institute of Diseases of the Chest proved inadequate for the research work that is being done there and a new building to accommodate the research departments has been built on the grounds of the Brompton Hospital for Diseases of the Chest, London. The institute has become a highly important center for training research workers and consultants in clinical medicine, particularly diseases of the chest. Important clinical advances by Dr. Neville Oswald and laboratory advances by Dr. Lynne Reid are being made in the study of bronchitis. Research in cancer of the lung and the biochemistry of cellular respiration by polarographic techniques is also being done.

Radiation Induced Cancer.—Eight more cases of radiation-induced cancer were described by Garrett (*Brit. M. J.* 1:1329, 1959). At first this was seen only in x-ray or radium workers, but in recent years cases have occurred in patients who have had radiotherapy for the treatment of benign as well as malignant conditions. All these cases were of laryngeal and pharyngeal carcinoma occurring in women who had had thyrotoxicosis treated by local irradiation of the thyroid gland many years earlier. The longest latent interval was 44 and the shortest was 20 years. According to Garrett a latent period of 44 years is probably the longest on record for a radiation-induced carcinoma of the larynx. In most of the patients described, the skin over the neck showed the stigmata of irradiation although in one, the first indication of a laryngeal lesion was pain in the throat and dysphagia. Carcinoma of the larynx and pharynx is not common in women, and if a woman has symptoms referable to these organs she should be asked whether her neck was treated with irradiation many years before.

Myocardial Infarction and Plasma Lipoprotein.—Dodds and Mills studied the lipoprotein pattern of blood at short intervals in 78 patients during a period of two months after myocardial infarction (*Lancet* 1:1160, 1959). Samples were taken when possible within 24 hours of the attack, three to four hours later, and thereafter at intervals of seven days. The average age of the patients was 58 years. The lipoprotein patterns were compared with those of 220 healthy men of the same age using ultracentrifugation, Cohn fractionation, and paper electrophoresis. The results showed that a myocardial infarction is itself associated with a pronounced lipoprotein abnormality, which is manifest for at least two months after the attack. The total plasma cholesterol and percentage of cholesterol in the β-lipoprotein of the blood was much above the normal figure, and the cholesterol in the α-lipoprotein was significantly lower. The atherogenic index was also elevated. These observations support the well-known hypothesis that coronary artery disease is associated with a high plasma cholesterol, low α-lipoprotein cholesterol, and high atherogenic index. Unfortunately, it was not possible to determine the lipoprotein levels before the attack of infarction. If these abnormal levels are present before an attack it is suggested that such estimations might be used to distinguish those who will contract coronary artery disease from those who will not. It seems probable from their data that myocardial infarction in men younger than 45 years of age is often preceded by detectable lipoprotein abnormalities which became more evident after the attack, whereas in the elderly it is more common to find the acute disease in men with normal lipoprotein patterns. The authors concluded that the blood lipoproteins were, in some patients, concerned with the development of coronary artery disease and that the infarct itself had an effect on the lipoprotein pattern.

Radiotherapy and High Pressure Oxygen.—A new unit for the application of radiotherapy to cancer patients breathing oxygen under high pressure, while anesthetized in a special chamber, was built at St. Thomas' Hospital in London. Cancer cells are more susceptible to the effects of radiation at high oxygen concentrations. A few years ago a preliminary trial was made of the effects of irradiating cancer tissue in patients breathing pure oxygen under three or four atmospheres of pressure. The investigation was temporarily abandoned when convulsions occurred in some of the patients. These have now been shown to be preventable by conducting the procedure with the patient under anesthesia. This provides the added advantage of keeping the patient still and free from apprehension. The new unit consists of a treatment room, control space, anesthetic room, laboratory, and staff room. The cobalt unit consists of two identical 2,000-curie cobalt-60 teletherapy heads mounted opposite each other. Fixed on rails in front of it is the pressure chamber. The monitoring apparatus includes an ECG; a microphone to follow respiration; a pneumotachograph which measures the flow, tidal volume, and minute volume of the respiratory gases; a plethysmograph to indicate the limb blood flow; apparatus for the automatic recording of blood pressure and temperature, including that in the chamber; an encephalograph for measuring the depth of anesthesia; and a polarograph for measuring tissue-oxygen tension.

Hereditary Alactasia.—A hitherto unrecognized congenital abnormality, an inability to hydrolyze lactose, was described by Holzel and co-workers (*Lancet* 1:1126, 1959). They observed two breast-fed siblings who failed to thrive, although their intake of milk was adequate. Lactose and glucose-plus-galactose absorption tests showed that glucose and galactose were readily absorbed by both infants, but that lactose was not. The ingestion of the latter did not lead to any significant increase in the blood level of monosaccharides, which is observed in normal infants. Since lactose is not normally absorbed as such but is hydrolyzed by intestinal lactose into glucose and galactose it was inferred that the specific lesion was a failure to hydrolyze lactose. As lactose is the only carbohydrate in any quantity in milk and constitutes 40% of the total caloric value, inability to utilize this sugar would explain the failure to gain weight. The infants gained weight when cereal and glucose were added to the feedings. As the enzyme defect occurred in siblings it was considered that the condition might be hereditary and the term hereditary alactasia was suggested for it.

New Androgen.—Clinical trials with a new androgen, fluoxymesterone, were described by Buckle (*Brit. M. J.* 1:1378, 1959). This is about 10 times as potent as methyltestosterone as it is active in oral doses of 2 to 4 mg. daily. The steroid was given to 10 patients; 2 of whom were eunuchs, 7 eunuchoids, and one of whom had pituitary infantilism. The potency of the drug was assessed on a subjective basis and the results compared with those obtained previously with methyltestosterone administered by mouth. None of the patients showed any sign of androgen deficiency while under treatment. Fluoxymesterone was fully effective when taken orally. It was no more active when given sublingually. Androgens have salt-retaining properties and it might be expected that fluoxymesterone, being a hydroxy-substituted steroid, would probably show this property to an exaggerated degree, but there was no evidence of edema.

Status of the Family Doctor.—In a research pamphlet issued by the Fabian Society, which is Socialist inspired, Dr. Bruce Cardew, the general secretary of the Medical Practitioners Union and editor of *Medical World*, strongly objected to family doctors having their offices in their homes. He believed very few houses are suitable for this as it constantly involves the doctor's family in the affairs of the practice. Most houses are limited in size and this determines how the doctor should practice medicine. There is seldom room for partners or additional staff. Patients become attached to a particular house and do not wish to go elsewhere with the result that the longer a doctor practices from his home the more difficult it is for him to move. The patient cannot help comparing the equipment and attention received in a modern hospital with that in the office of the family doctor, and consequently the status of the physician whose office is in his home is lowered in the eyes of his patients. From the doctor's point of view such an office has much in its favor. It is cheaper, it reduces traveling time, and patients become attached to the home and the wife as well as to the doctor, so that if a new doctor comes the patients continue to attend. At present 80% of family doctors practice from their homes.

Far too many doctors are forced to lower their clinical standards because they are ill-equipped and have not the time to practice good medicine. If they had fewer patients to care for, were better housed, better organized, and in closer touch with other health and welfare agencies, they could give their patients more attention, could relieve the hospitals of much of their work, and would reduce much of the sickness benefit now paid out from national insurance funds.

In 10 years, only 10 health centers for group practice by doctors have been built. In these centers 100 physicians serve 100,000 patients. Dr. Cardew states that in terms of achievement, health centers must be said to have failed. He hopes that the next Labor government will set aside enough money for experiments with health centers so that more experience may be gained. While experiments with health centers continue, other ways must be found of improving standards of general practice. From the doctor's point of view group practice is the more attractive. It is based on a voluntary association of members with a common aim. It enables groups to select their points of practice, to plan the layout of the buildings to their own requirements, and to choose their own secretaries and receptionists. The doctors own and control their practices and cannot be interfered with.

Suggested Ban on Boxing.—In its editorial of June 6 the *Lancet* advocated the total abolition of boxing by law because of the health hazards attached to it. Deaths continue to occur in the ring, usually from gross injury to the brain or its vessels. A young boxer, who had a wife and children, recently died in Windsor Hospital after being knocked out in an amateur tournament, and a welterweight champion, aged 24, incurred an intracranial hemorrhage. Time and again it has been stressed that the path of boxing can lead to brain damage, imbecility, blindness, and death, yet nothing is done to stop it. On the contrary, official bodies such as the British Broadcasting Corporation extend the spectacle on television to ever-widening audiences, inclusing young children. According to the *Lancet* 64 deaths, including 22 in amateurs, in four years is a heavy price to pay for a sport which makes the brain its chief target.

The medical case against boxing is now so strong that doctors have a clear duty to fight for its total abolition, but they would have to contend with the vested interests concerned, with the strong and thoroughly unhealthy, though largely subconscious, public appetite for violence and bloodshed, and with the indifference of the public. It is suggested that one or more of the medical bodies in Britain should follow the Belgian example of persuading the government to pass stringent legislation against boxing before television audiences see some unsuspecting youth battered to death in the ring. Asked about the possible ban, the British Medical Association stated that it had no official policy in the matter. The medical officer of the British Boxing Board of Control said that most stringent regulations had been drawn up and that before a boxer was issued a license he had to pass stiff medical tests. His health and career were carefully watched from the time he put on his boxing gloves. Everything humanly possible was done to safeguard his health. Unless fit, he was not allowed to fight. From the point of view of an insurance hazard, boxing is classified with basketball and ice hockey and is rated as less dangerous than American football, polo, or even scull rowing.

Tuberculosis in the Elderly.—Pulmonary tuberculosis is increasingly becoming a disease of older persons, and particularly of men over 65 years of age. The number of reported cases in men over this age has almost doubled in the last 16 years. Mass radiography surveys show that the yield of active tuberculosis cases is 7 per 1,000 examined in those over 60, compared with 4.37 per 1,000 examined in persons under this age. It is generally thought that tuberculosis in older persons is a very chronic disease, but according to Smith some older persons have a clear chest film and then subsequently develop active tuberculosis (*Brit. M. J.* 1:1448, 1959). In a series of 100 persons over the age of 55 years diagnosed by him as having pulmonary tuberculosis 49 had had a previous chest film taken when they were more than 45 years old. The first film of 23 of these 49 patients, or 46%, showed no evidence of intrapulmonary disease, and many of them had been radiographed within five years of diagnosis.

It, therefore, seems that a clear chest film in an older person is of limited value only. If there is any suspicion of pulmonary tuberculosis in those in the older age group it is, thus, essential to radiograph the chest, even if a fairly recent film had been reported clear. Certainly radiological reports of "bronchitic changes" and "unresolved pneumonia" should be regarded with suspicion from the point of view of both tuberculosis and lung cancer. Many so-called new cases of tuberculosis in older people are due to breakdowns of old lesions regarded as inactive on previous radiographic examination. Reactivation of lesions not radiologically visible also occur.

What is not generally realized is that, contrary to the usual course of events, younger members of a household may infect the older ones. Regular mass surveys of older persons are advocated, although it is notoriously difficult to persuade them to submit to this. Lassitude, anorexia, and loss of weight, too often regarded as normal features of advancing years, may be the only symptoms of pulmonary tuberculosis in the elderly. Cough, if it occurs, is frequently attributed to "bronchitis" or smoking. Smith advised that the appearance of the above symptoms, with or without pulmonary involvement, calls for radiographic examination of the chest, even if a recent film had been reported clear.

Cross-Infection in Hospitals.—Cross-infection due to antibiotic-resistant strains of Staphylococcus pyogenes phage type 80 is now a matter of concern in many hospitals. A hospital epidemic due to this organism was described by Williams and co-workers (*Brit. M. J.* 1:1374, 1959). Swabs taken from wounds, the anterior nares and the skin of patients, and from the nares of hospital staff members were cultured. Blankets were also examined for bacterial contamination. Primary infection of the skin causing boils and furuncles in adults, and conjunctivitis and pemphigus in the newborn, accounted for 46% of all infections and 53% of those due to Staph. pyogenes phage type 80. Cross-infection of wounds and secondary infection of the respiratory tract caused most of the other cases. Nearly 15% of healthy nurses were infected on the skin and 51% were nasal carriers. Over 30% of the medical staff had positive nasal swabs. Nearly all operative wounds were found to be free from infection for the first few days, but many became secondarily infected with tetracycline-resistant Staph. pyogenes phage type 80. Cross-infection with tetracycline-resistant staphylococci phage type 80 was also found to be frequent in the hospital outpatient department.

Attempts at wholesale elimination of the infection were undertaken. Walls, ceilings, floors, and furniture were washed with an antiseptic-detergent mixture, and all utensils were steam sterilized or disinfected. Blankets were disinfected, hands washed with hexachlorophene soap and treated with 1% chlorhexidine hand cream, and nasal carriers treated intranasally with 0.5% neomycin ointment for a month. Carriers among the patients were bathed three times daily. In spite of these measures, they failed to reduce the incidence of cross-infection, although the carrier rate was reduced. It was impossible to isolate all carriers. Widespread infection of a hospital with such a resistant strain leads to increased risks to patients admitted for any reason and to increased septic lesions in the nurses. Failure to reduce cross-infection was attributed largely to increased foci of infection with Staph. pyogenes phage type 80 and other tetracycline-resistant strains in general practice. Ideally, persons so infected should be identified before hospitalization and then isolated.

Breast Cancer.—A new approach to the treatment of breast cancer has been made by Watson and Turner, who treated a series of 34 patients by the simultaneous administration of testosterone and thio-TEPA, an antimitotic alkylating agent known to be lethal to the cells of breast cancer (*Brit. M. J.* 1:1315, 1959). Oophorectomy was also performed before treatment in premenopausal patients. To one group an aqueous solution of 15 mg. of thio-TEPA was given intramuscularly two or three times a week until the leukocyte count fell below 3,000 per cubic millimeter. Treatment was then stopped and resumed when the leukocyte count returned to pretreatment levels. Another group received 30 mg. of thio-TEPA on alternate days until a total dose of between 180 and 300 mg. was given, depending on the response and leukocyte counts. After the completion of this course the patient rested for three to six weeks and then a similar course of treatment was given. Some patients were put on a maintenance dose of 15 to 30 mg. of thio-TEPA at intervals of two to four weeks; 200 mg. of testosterone propionate was given intramuscularly five times a week, beginning one week before the course of thio-TEPA therapy and continuing for two weeks after its completion. Six patients with pleural and peritoneal effusions had 30 mg. of thio-TEPA instilled directly into the cavity after paracentesis in addition to their normal course of intramuscular injections. Adjuvant therapy such as transfusion with concentrated erythrocytes for anemia or cortisone for thrombocytopenia was given when necessary.

Only those patients with widely disseminated lesions or with recurrences after radiation or operation were so treated. Before commencing treatment a clinical, radiologic, and hematological survey was made, and estimations were made of the presence of C-reactive protein, sedimentation rate, plasma proteins with their electrophoretic pattern, blood uric acid level, alkaline phosphatase level, and daily urine calcium level. Progress was recorded every 14 days. Tumor masses were measured and visible lesions were photographed. Simple mastectomy was performed on 11 previously untreated patients.

The most satisfactory results were obtained in those patients receiving both thio-TEPA and testosterone. Marked inhibitory effects were obtained in 30 patients, that is in 88%, which compares favorably with the accepted figure of 33% for treatment with testosterone alone. There was some evidence that testosterone protects normal marrow and normal growing tissues against the depressive action of thio-TEPA, which can then be given in larger doses. The authors suggested that a compound might be made incorporating the ethylenimino group of thio-TEPA with testosterone. They stated that the clinical, histological and radiologic evidence of destruction of malignant cells obtained in the advanced cancers of their series pointed to the possibility of completely eradicating a tumor and its metastases by chemotherapy. They believed that a wider use should be made of chemotherapy as an alternative to radiation in the treatment of breast cancer. They advocated a trial of surgery and chemotherapy instead of surgery and irradiation.

CORRESPONDENCE

ARCHIVES OF ERRORS

To the Editor:—The Council on Clinical Chemistry of the American Society of Clinical Pathologists has established an *Archives of Errors* for the accumulation and dissemination of errors in leading textbooks and journals relating to clinical pathology. Most persons in the practice of clinical pathology are aware that corrections of published errors pertaining to laboratory tests are often not published by textbooks and journals. The Council on Clinical Chemistry hopes to accumulate a list of some of these errors for distribution to people working in the laboratory so that they can profit by the mistakes and corrections of others.

Letters were written to the authors of leading textbooks on clinical pathology asking their reaction to such a program; the response was enthusiastic. To date, errata sheets on two textbooks have been made available; one is Annino's "Clinical Chemistry: Principles and Procedures" (Boston, Little Brown & Company, 1956), and the other is Knight and others' "Ultramicro Methods for Clinical Laboratories" (New York, Grune & Stratton, Inc., 1957). Pathologists and people working in laboratories will supply data on errors which they have noted and corrected in books and journals. These methods can then be made available to other people working in the field. At present, if a report of error is received by the editor, it is forwarded immediately to the author for checking. If the author concurs, the correction is sent to the office of the American Society of Clinical Pathologists for publication in its bulletin. Through the cooperation of all people working in clinical pathology, this program can be expanded into a useful, central clearing house for the benefit of all physicians.

Persons having information on errors and pathologists interested in working with the committee as part of the program should contact the editor of the *Archives of Errors.*

MICROSCOPIC HEMATURIA

To the Editor:—In a widely circulated recent brochure the statement was made that the centrifuged urinary sediment may normally contain 4 to 10 red blood cells per high-power field. It was the immediate reaction of urologists in our department that this figure was too high and that if it were taken as normal many significant lesions in the urinary tract would be missed. A review of the subject of microhematuria was then undertaken in an effort to determine the number of red blood cells per high-power field considered to be within normal limits by most authorities.

Inspection of the standard textbooks in laboratory diagnosis, urology, and internal medicine revealed remarkably few statements as to the exact number of red blood cells permissible in the normal centrifuged urinary sediment. Thomas Addis states in his book "Glomerular Nephritis: Diagnosis and Treatment" (New York, The Macmillan Company, 1948) that "we should see nothing or next to nothing in the volume inspected on a quantitative slide unless renal disease, and disease of a certain intensity, is present. Now and again it might happen that we come across a red cell, or even, conceivably a hyaline cast in a normal urine, but that accident would only make it necessary that we go farther and look at several unit volumes."

Greene, at the Mayo Clinic, found that, in a group of patients with asymptomatic microscopic hematuria with 1 to 10 red blood cells per high-power field, 55% had a definite abnormality in the urinary tract, such as hemorrhagic cystitis, renal calculi, or a bladder neoplasm.

On the basis of a medical-actuarial impairment study conducted by the New York Life Insurance Company in 1951, it was found that the mortality increases in direct proportion to the number of red blood cells in the urine. If there are more than five red blood cells per high-power field the mortality is increased sufficiently to warrant increasing the premium for these life insurance applicants.

It is the opinion of those interested in diseases of the urinary tract and in laboratory diagnosis at the University of Michigan Medical School that more than one red blood cell per rare high-power field in a routine centrifuged urinary sediment must be considered abnormal. This is the value that the sophomore medical students are taught in their course on clinical microscopy. We believe that any patient with more than one red blood cell per rare high-power field on repeated urinalyses should have a complete urologic investigation, even in the absence of urinary symptoms.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

The Value of Electrocardiography When Coronary-Artery Disease Is Suspected. J. W. Todd. Lancet 1:845-848 (April 25) 1959 [London].

Electrocardiography cannot help in deciding whether or not a patient has anginal pain of effort. It is of small or doubtful value in determining both causation and prognosis when anginal pain is present. When a patient gives a history of attacks of precordial pain of an indeterminate character, electrocardiography is sometimes of considerable help. In differentiating between emotional cardiac symptoms and anginal pain of effort, the electrocardiogram is valueless. When cardiac infarction is suspected, electrocardiography gives unequivocal guidance if the characteristic electrocardiographic changes of recent infarction are present. But the electrocardiogram reflects only imperfectly the gravity and extent of the process in the heart, and a normal electrocardiogram cannot exclude infarction. Used routinely, electrocardiography may enable insurance companies to refuse to insure life, or enable employers to refuse someone employment. It is useless to the person concerned and, by bringing to light minor abnormalities, may make it possible for an unwise physician to turn the person into an invalid. The interpretation of electrocardiograms is often difficult, there being great variation between the reports of different experts on the same tracing, and considerable variation in the reports of the same expert on the same tracing at different times.

These considerations suggest that electrocardiography has been greatly overvalued in the investigation of patients with suspected coronary-artery disease. There are 2 main reasons for this overvaluation: 1. Because fatal and severe coronary-artery diseases are both undeniably important, one tends to assume the importance of determining whether or not a patient has minor coronary-artery disease. The presence of such disease neither provides a good reason for giving treatment nor enables an accurate prognosis to be made. Because the importance of the problem is exaggerated, the importance of the means which is thought to solve it, i. e., electrocardiography, is exaggerated in turn. 2. Among all the machines used for diagnosis, the electrocardiograph is the most impressive, but the readings supplied by the machine are useful only when interpreted by man, and this interpretation is not always simple. Even if in diagnosing cardiac infarction the electrocardiographic evidence alone is superior to the other evidence alone, in practice all the available evidence should be considered together.

Reduction of Serum Cholesterol Levels and Beta-Lipoprotein Cholesterol Levels by Nicotinic Acid. W. B. Parsons Jr. and J. H. Flinn. A. M. A. Arch. Int. Med. 103:783-790 (May) 1959 [Chicago].

Studies on cholesterol-fed rabbits in 2 laboratories have shown that nicotinic acid not only reduced serum cholesterol levels but resulted in partial (and often striking) protection against atherosclerotic lesions of the aorta. Conclusions drawn from these studies, though, cannot be transferred to humans. The use of large doses of nicotinic acid must be evaluated by controlled studies over many years before its effect on human atherosclerosis and its complications will be known. Such studies are in progress at the authors' clinic and elsewhere. Excluding those still in the first 24 weeks of therapy, the authors present their experience with 44 patients studied for periods of up to 2 years. Only the data from the first 56 weeks of treatment were considered in this report.

It was found that serum cholesterol levels can be reduced in the majority of hypercholesteremic patients by administration of large doses of nicotinic acid while the patients continue to eat their usual diets. The reduction is most prominent in the beta-lipoprotein cholesterol fraction, with reduction of the beta/alpha$_1$-lipoprotein cholesterol ratio. Nicotinamide is ineffective in reducing serum cholesterol levels. The only significant side-effects after ingestion of nicotinic acid are flushing and pruritus, which subside rapidly in the early stages of therapy and have not interfered with therapy. No toxic reactions have been found by clinical and laboratory observations, including a battery of 7 tests of hepatic function and needle biopsies of the liver in 17 patients after one year of therapy. Study for a much longer period will be required to determine

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

whether this form of therapy for hypercholesteremia will prevent or retard the progression of atherosclerosis in humans as it does in cholesterol-fed rabbits.

Interest and Importance of the Laboratory in the Management of Streptococcic Endocarditis. R. Martin, Y. Chabbert, B. Sureau and L. Martin. Presse méd. 67:667-670 (April 4) 1959 (In French) [Paris].

Various streptococci are capable of causing subacute bacterial endocarditis. Even those streptococci which are considered to be common and nonpathogenic saprophytes can be agents of this infection. The study of the bacteriostatic power with the classic antibiogram often results in the prescription of an antibiotic which is not the best choice. Therefore, it is necessary to interpret laboratory results and to ask for a quantitative study of the bacteriostatic power in liquid medium. Study of the bactericidal power of an antibiotic, or antibiotics in combination, is of great importance for the management of treatment and for prognosis. Penicillin and streptomycin are the antibiotics with the greatest bactericidal power. The penicillin-streptomycin combination is generally recommended for treating patients with group D streptococcic endocarditis. Penicillin alone is often sufficient in treating the form due to alpha-hemolytic streptococci. If the bactericidal action of the antibiotic, or antibiotics' combination, leaves a 1/1,000 survival of micro-organisms, therapeutic failure is possible; on the contrary, a rate of survival of 1/10,000 is favorable.

The "cellophane transfer" technique for the determination of the bactericidal power of antibiotics has the advantage of permitting photographic records which may be preserved and compared in case of variations in strain behavior. When endocarditis fails to respond well to treatment, a determination of antibiotic action may be performed on the patient's blood. Agreement between laboratory data and therapeutic results is obvious, as may be seen from the authors' statistics concerning 81 cases of streptococcic endocarditis. In 70% of the cases there was complete parallelism between the laboratory and the clinical course; 12% of the cases were not in agreement, and 18% were difficult to interpret.

Serum Transaminase in Diagnosis and Prognosis of Myocardial Infarction. K. Bobek, V. Karliček and V. Lahn. Ztschr. ges. inn. Med. 14:327-331 (April 1) 1959 (In German) [Leipzig, Germany].

The authors report on 70 men and 30 women, between the ages of 34 and 83 years, who were admitted to the medical clinic of the University in Plzeň, Czechoslovakia, for sudden pain in the chest or epigastrium. Immediately on admission blood specimens were obtained from these patients, and serial estimations of the concentration of serum glutamic oxalacetic transaminase (SGO-T) and serum glutamic pyroracemic acid (SGP-T) were made with the aid of the colorimetric technique at least once, but occasionally several times, daily for 3 consecutive days. In 41 of the 100 patients, the electrocardiogram showed myocardial infarction; the clinical picture and such laboratory findings as increased erythrocyte sedimentation rate, leukocytosis, and shortening of the coagulation column suggested myocardial infarction in 13; 26 patients had angina pectoris without signs of myocardial infarction; and in the remaining 20 other causes of the attack of pain, such as pulmonary embolism, bronchial pneumonia, rheumatic carditis, and necrosis of the pancreas, were observed.

Of the 54 patients with acute myocardial infarction, the transaminase activity was determined in 51 in time, and in all of these a significantly increased concentration of the SGO-T by 205 units, on the average, was noted. The serum transaminase values of the patients with angina pectoris were normal. A rise in the SGO-T level also was observed in the patients with pulmonary infarction, rheumatic carditis, and acute necrosis of the pancreas. Three of 9 patients with myocardial infarction, in whom the rise in the SGO-T level exceeded 300 units, died, and 4 had a severe course. The course of myocardial infarction was milder in 27 patients in whom the SGO-T activity varied between 100 and 300 units, and only one of these patients died. None of 15 patients with a SGO-T activity of less than 100 units died, and all of them had a mild course.

Serum glutamic oxalacetic transaminase estimations have a definite place in the diagnosis of myocardial infarction. A sudden rise and drop in the SGO-T activity favors with high probability the presence of myocardial infarction. Normal findings at the critical time are, with even greater probability, suggestive of the absence of myocardial infarction. The rise in the SGO-T activity and its duration also permit conclusions concerning the approximate extent of the necrosis and are, with the aid of other findings, of prognostic value.

Familial Cardiomegaly. G. Faive, J. Gilgenkrantz and J. Panthu. Presse méd. 67:673-676 (April 4) 1959 (In French) [Paris].

Familial cardiac hypertrophy, a recently described condition, is characterized by the presence of an enlarged heart, with no defined etiology, in a certain number of members of the same family. The authors examined 9 members of a family and found 3 cases in which there were electrocardiographic changes typical of hypertrophy and left ventricular overload with or without ischemic lesions. In the same family there were 2 cases of isolated enlargement of the heart without electrocardiographic alterations. No infectious or metabolic etiology was detected in 2 members even by means of intracardiac catheterization.

The disease is usually discovered between the ages of 20 and 25 years. There is no functional symptomatology in more than one-third of the cases; the minor symptomatology in the remaining two-thirds is characterized by effort dyspnea, rhythmic disturbance, lipothymia, or even syncope, frequently appearing rather late in the course of the disease. In more than one-half of the cases objective signs are in the form of a systolic murmur on auscultation. Radiologic examination is most important. Cardiac hypertrophy is global in about half of the cases, and left ventricular in the other half. A certain number of alterations reappear frequently in the electrocardiogram, giving a "family style" to all recordings. These alterations consist of changes in the ventricular complex and in the repolarization phase and of rhythm disturbances. Progress of the disease is considered less severe than formerly.

It is not known whether cardiac hypertrophy is an isolated form of a muscular or general metabolic illness or whether only the cardiac muscle is affected. It is likely to be hereditary. It is necessary to carry out a systematic familial inquiry when a primary enlarged heart is detected in a young subject.

Primary Hyperparathyroidism. J. Hellström. Nord. med. 61:551-556 (April 9) 1959 (In Swedish) [Stockholm].

The pathological changes in primary hyperparathyroidism consist of either adenomatous enlargement of usually one parathyroid gland or a so-called hyperplasia of all the glands. The cause is not certain. While the disease is relatively rare, the author's material was comprised of 112 cases, studied from 1930 to 1957 in patients aged from 16 to 71 years; 80% of the patients were women. Symptoms were often present for a long time before diagnosis was made. Calcification or stones in the kidneys were the commonest symptoms. Renal changes, alone or together with skeletal changes, were seen in 85% of the cases. Renal injury was present in all the cases of hyperparathyroidism, and there was more or less marked impairment in the concentration ability of the kidneys. A normal concentration test almost surely excluded hyperparathyroidism. In early cases the inability to excrete concentrated urine was of functional nature and could disappear after a successful parathyroidectomy. Hypertension, regarded as secondary to the renal changes, occurred in 70% of the cases. In earlier cases the hypertension was moderate and variable; later it became marked. In several cases it caused death or incapacity because of cerebral complications. The most typical skeletal change in hyperparathyroidism was osteitis fibrosa generalisata, considered pathognomonic for hyperparathyroidism. Marked osteitis was seldom seen. The skeletal changes always healed functionally if not anatomically. In 8 cases the first symptom of the disease was a giant-cell tumor in the upper or lower jaw. Gastroduodenal ulcer occurred in 33% of the male patients and in 3% of the female patients.

Diagnosis depends on clinical symptoms and on roentgenologic and laboratory examinations. The prognosis in untreated hyperparathyroidism is unfavorable. There may be so-called acute hyperparathyroidism with foudroyant course, or the course may extend over a long period, with recurring kidney stone and infection of the urinary tract. Spontaneous remissions occur, but certain recovery is unknown. The only rational treatment is excision of the hyperfunctioning parathyroid tissue. Internal treatment can be only symptomatic, and roentgen-ray treatment has been without avail. Operation may be simple when there is a solitary adenoma in the usual location; otherwise, it is difficult. In 22% of the cases reviewed, operation was unsuccessful or incomplete because of abnormal location of the adenoma, adenoma so small as to escape notice, or confusion with lymph glands or thyroid adenoma. Special difficulties are met with in primary hyperplasia, where all the parathyroid glands must be removed and only enough parathyroid tissue left to prevent insufficiency. The prognosis after parathyroidectomy depends on the degree of renal damage at the time of operation. Treatment should be centralized in hospitals equipped with the best facilities for scientific examinations, and operations should be performed only by surgeons experienced in thyroidectomy.

Antistreptolysin Titration in Certain Varieties of Glomerulonephritis: The Clinical Value of the Antistreptolysin O Titer. V. Scaffidi and A. Janni. Minerva med. 50:673-678 (March 7) 1959 (In Italian) [Turin, Italy].

The serum antistreptolysin O titer was measured in 31 patients with the following varieties of glomerulonephritis: diffuse acute or subacute variety (4 patients), localized acute or subacute variety (3), localized variety with tendency of the symptoms to recur and to become chronic (2), localized asymptomatic glomerulonephritis with tendency to become chronic (2), development of proteinuria after nephrotic or tonsillar syndromes (4), chronic glomerulonephritis associated with renal insufficiency (6), and other kidney diseases (10). Among the patients with the diffuse acute or subacute variety of glomerulonephritis, normal concentration of serum antistreptolysin O was observed in those instances in which the presence of hemolytic streptococci could not be established, and high concentration was observed with the presence of hemolytic streptococci. The hemolytic streptococcic origin of glomerulonephritis was also established in patients with the localized acute or subacute variety of the disease, although the serum antistreptolysin O titer was not so marked as in patients with the diffuse variety of the disease. There seemed to exist a certain correlation between the clinical course of glomerulonephritis and the antistreptolysin O titer. The titers returned within normal limits in patients in whom remission of the disease was rapid and complete. They persisted to be high, after remission of the acute phase of the disease of streptococcic origin, in those in whom the symptoms tended to become chronic. The values returned within normal limits only after complete remission of the disease took place. The titers were normal or were slightly elevated in patients with the chronic phase of the disease associated with renal insufficiency. This study suggests a close watch of patients who have had glomerulonephritis and in whom the antistreptolysin O titer persists to be high. The observance should last until there is complete normalization of the antistreptolysin O titer.

Facial Actinomycosis Misdiagnosed as Tetanus. J. Graham, K. Malmberg, R. Patey and A. Rubenstein. Illinois M. J. 115:271-273 (May) 1959 [Chicago].

In the 33-year-old man whose history is presented, the jaw muscles stiffened gradually until he was barely able to open his mouth. Four and one-half weeks previously he had "mashed" his left index finger on a grinding wheel, for which he had been treated and given a "tetanus shot." His canine teeth could not be opened more than three-eighths of an inch, and there was tenderness over the left masseter muscle. The left index finger was swollen, red, and tender, and there was a subungual hematoma. The patient was hospitalized, and the nail of the injured index finger was removed, and the area débrided. Cultures taken did not yield Clostridium tetani, but the patient was given 100,000 units of tetanus antitoxin and 1.2 million units of penicillin daily. Motion of the jaw improved, and he was discharged 5 days later.

Ten months later, in August, 1957, the patient's jaw again became tight. Examination now revealed a localized enlargement on the masseter muscle. The patient was treated with corticotropin and muscle relaxants for 4 weeks, but there was no improvement. The palpable mass was explored; the masseter muscle was split in the direction of its fibers. When the fascia was split, an encapsulated area of necrotic debris was found, which was removed by a curet. The area was drained, and nystatin (Mycostatin) powder was instilled. The debris contained a 3-mm. mass which was hard and yellow. The pathological report confirmed the suspicion of actinomycosis, as did the culture of the material. The patient was treated in hospital, with daily doses of 1,000 units of Mycostatin, 1.2 million units of penicillin, 1 Gm. of Chloromycetin, and a saturated solution of potassium iodide. The patient was discharged after one week, but daily injections of 1.2 million units of penicillin were continued for several months. Nine months later there had been no further recurrence of actinomycotic activity.

In retrospect, the authors say that the patient did not have the typical picture of tetanus; but when they were faced with the combination of a crushing, infected wound of the finger associated with trismus, and no other apparent cause for trismus, tetanus was considered. The possibility of actinomycosis should be kept in mind in obscure conditions around the cervicofacial area, particularly when a mass or infiltration is palpable. Treatment with penicillin or other antibiotic, combined with surgical excision, should be vigorous.

Nocardia Asteroides Infection: A Report of 7 Cases. M. C. Larsen, H. D. Diamond and H. S. Collins. A. M. A. Arch. Int. Med. 103:712-725 (May) 1959 [Chicago].

Nocardiosis is a granulomatous and suppurative infectious disease caused by the aerobic actinomycete, Nocardia asteroides. The authors report 7 new cases of this infection, the patients being treated at the Memorial Center for Cancer and Allied Diseases, New York, between 1952 and 1957. Attention is called to the presence of neoplastic disease in 5 of the 7 patients. The first case was of interest because the lesion was in an anatomic site previously unreported—the breast—and because of the likelihood that infection was exogenously introduced by a rose-thorn abrasion. Surgical extirpation, not antibiotic therapy, was credited with the cure in this case. The second patient was admitted because of chronic cough productive of thick, yellow, blood-streaked sputum. These symptoms were the residua of a severe pneumonia treated 5 weeks previously. Bronchoscopy revealed neither malignant cells nor tubercle bacilli. A large cystic cavity was observed 3 months later in the lobectomy specimen, and a sputum sample, obtained just before the operation, grew N. asteroides. The pathologist then restained the tissue sections with a modified Gram technique. Inspection showed gram-positive branching forms compatible with actinomycetes in the borders of the pulmonary abscesses and invading the lung parenchyma, thus establishing that Nocardia organisms played at least a partial role in causing the destructive lesions.

In the third patient, autopsy disclosed leukemic infiltrates in various organs; the presence of a grayish-yellow subpleural abscess in the right middle lobe of the lung was of special interest. A smear showed beaded, filamentous, long rods, some of which branched; on culture these were identified as N. asteroides. The fourth patient had chronic myelogenous leukemia; N. asteroides was isolated from 2 of 3 blood cultures during his last week of life. The fifth patient had been observed and treated throughout a 12-year period after radical mastectomy for carcinoma of the breast. Six months prior to death, hypophysectomy was performed to arrest metastatic disease. Twelve days before death deterioration began, with chills, myalgia, nausea and vomiting, lethargy, giddiness, and a sensation of retro-orbital fulness. At post mortem no tumor metastases were found in the brain, but a multiloculated abscess cavity contained greenish purulent material, which yielded N. asteroides in pure culture.

In the sixth patient, a man with chronic lymphatic leukemia of 4 years' known duration, a lung abscess developed. This was a remarkable instance of infection due jointly to Nocardia organisms and Diplococcus pneumoniae. Despite the persistent sensitivity of the Nocardia to chlortetracycline in vitro, and the disappearance of the organisms from the sputum during treatment with this agent, subsequent examination of the lung demonstrated that the infection had not been eradicated. The nocardial infection was cured by surgical extirpation and not by antimicrobial therapy. The seventh patient was a woman treated for generalized Hodgkin's disease over a 13-year period. Autopsy revealed numerous nodules in the lungs with central necrosis due to Nocardia. Similar lesions were found in the liver, pancreas, kidneys, and brain; cultures yielded N. asteroides. Surgical extirpation of the nocardial lesion produced cure in 3 instances. Death was considered due primarily to nocardiosis in 2 patients and to cancer in 2 others. Antibiotic therapy alone was not successful in eradicating the infection. The literature now suggests that sulfonamides might have proved more effective.

The Effects of Vitamin D and Gluten-Free Diet in Idiopathic Steatorrhoea. J. R. Nassim, P. D. Saville, P. B. Cook and L. Mulligan. Quart. J. Med. 28:141-162 (April) 1959 [London].

The treatment of celiac disease in children has been revolutionized since the observation of Dicke in 1950 demonstrated that the condition improved when the flour of wheat and rye was excluded from the diet. It was also shown that on this regimen fecal fat was reduced, and that the harmful effects of the flour were due not to the starch but to the protein (gluten) fraction. Later gluten-free diets were also tested in adults with idiopathic steatorrhea or with tropical sprue. It appeared that, whereas in infants and children the response to a gluten-free diet is universally good, only a proportion of adults may expect to be improved. With regard to the calcium balance in steatorrhea and the response to vitamin D, opinion is still not crystallized. The present paper concerns metabolic studies conducted in an attempt to provide further information concerning the actions of vitamin D and its relationship to gluten.

A consecutive series of 9 patients (2 male and 7 female) were studied. Their ages ranged from 8 to 60 years. All the patients were admitted to the metabolic unit of the Royal National Orthopedic Hospital in London. They were not confined to bed. In order to reduce the tedium of the diet, 3 daily menus were prepared and given in constant order of rotation. All the food was weighed, and the calculated daily values for calcium, phosphorus, nitrogen, and fat were made virtually identical in the 3 menus. The gluten-free diet produced clinical improvement in all the patients. The discontinuation of a gluten-free diet was usually followed by a violent clinical and biochemical relapse. The patients appeared to be very resistant to the action of vitamin D given orally or parenterally. There was evidence of increased sensitivity to the action of vitamin D when it was accompanied by a gluten-free diet, irrespective of the state of fat absorption. The level of serum inorganic phosphorus tended to be low before treatment, and 6 patients showed a definite increase in serum inorganic phosphorus after treatment with gluten-free diet or vitamin D. The calcium balance was studied in 7 patients. Four were in positive balance before treatment was begun. The calcium balance seemed to bear no relation to the degree of steatorrhea. Osteomalacia (pseudofractures or active rickets) was present in 5 patients; 3 of these patients had strongly positive calcium balances. A negative calcium balance was present in one patient without evidence of osteomalacia.

No consistent relationship could be demonstrated between the degree of steatorrhea and calcium absorption. All the patients who had good calcium absorption at the time of study had active osteomalacia. It is suggested that such patients pass through phases of positive and negative calcium balance, and that this phasic variation is not related to the degree of steatorrhea, but may be related to the degree of parathyroid activity. A marked increase in serum inorganic phosphorus followed treatment in 6 cases. It is suggested that this increase is a manifestation of parathyroid inhibition. The hypothesis that malabsorption of calcium in gluten enteropathy is due to a primary absorption defect was not supported by the data presented. Though there may well be such a defect, there is also a defect of intermediary metabolism involving vitamin D. Although the response to a gluten-free diet was favorable in every case, reversion to a normal diet resulted in a relapse to a degree of steatorrhea more severe than the original untreated condition. The advice to patients to take a gluten-free diet must, therefore, be tempered by the possibility that they may be worse if they are unable to maintain it.

Whipple's Disease: The Clinical Aspects. P. Farnan. Quart. J. Med. 28:163-182 (April) 1959 [London].

Whipple described the first case of the disease now referred to as intestinal lipodystrophy at Johns Hopkins Hospital in 1907. Farnan states that, of the total of 46 cases reported from America, 28 have been observed since 1950. He discusses the clinical aspects of the disease on the basis of 7 cases of intestinal lipodystrophy observed in Britain and of 60 other well-documented cases. The disease occurred predominantly in men (55 of 67 patients) of an average age of 43 years. The clinical pattern may be divided into a prodromal period, characterized by exacerbation of illness, and a final period of relatively rapid decline. Six features, all of them intermittent, are observed during the prodromal phase: arthritis, abdominal symptoms, diarrhea, cough, loss of weight, and asthenia. The prodromal phase in the 7 cases presented ranged from 2 or 3 years to 23 years, whereas the final period of decline lasted from 3 to 18 months. The disease may be more common than is suspected, and should be included in the differential diagnosis of the steatorrheas and chronic diarrheas.

The fully developed picture often suggests Addison's disease, but the absence of electrolyte disturbances should allow intestinal lipodystrophy to be considered. The main physical signs are usually found on abdominal examination. The triad of distention, upper abdominal mass, and radiologic evidence of gastric or duodenal displacement, or any 2 of these features, may be of help in diagnosis. Supporting evidence may be available in the cardiovascular or respiratory system. The results of laboratory investigations parallel those found in idiopathic steatorrhea; but the invariable presence of a normochromic or hypochromic anemia, the finding of occult blood in the stools, and the common association of gastric achlorhydria may help to differentiate the conditions. The diagnosis must be confirmed by the demonstration of the characteristic Schiff-positive macrophages. This may often require biopsy of the mesenteric lymph nodes, but the macrophages have also been demonstrated in the peripheral lymph nodes, and lymphadenopathy with an indefinite "sarcoid-like" picture should stimulate biopsy studies on lymph nodes. The basic lesion appears to be an alteration in the ground substance of the mucosa of the jejunum. Its periodic formation and dissemination may account for the protean symptoms of the prodromal period and for the extensive lesions found at autopsy; later, when produced in excess, it appears to cause obstruction of the lacteals at the mucosal site and the clinical features of a general malabsorption defect.

Until the advent of steroid therapy little could be done for these patients. The results of steroid therapy are capricious, but remission of some degree appears to be the rule, though eventually it is followed by relapse and death. There are no grounds for assuming a pituitary-adrenal mechanism to explain the main features of the condition. The demonstration by Black-Schaffer in 1949 of a mucopolysaccharide complex in the macrophages in the jejunum caused a reorientation of etiological concepts, and it now appears likely that the jejunal mucosa represents the source of the process.

Adult Leukaemia: Trends in Mortality in Relation to Aetiology. W. M. C. Brown and R. Doll. Brit. M. J. 1:1063-1069 (April 25) 1959 [London].

The deaths from leukemia which occurred in England and Wales for the period from 1945 to 1957 have been classified under 3 headings: (1) acute leukemias of all types; (2) chronic myeloid leukemia; and (3) chronic lymphatic leukemia. The age-specific mortality rates have been calculated for each type of leukemia, for each sex, and for 3 periods of time—1945-1949, 1950-1954, and 1955-1957. The data have been gathered for persons aged 15 years and over. Deaths attributed to plasma-cell leukemia have been excluded. It has been shown that, for each of the 3 periods studied and for each of the 3 different classes of leukemia, there was an appreciable increase in mortality with age during a large part of adult life. There was, however, an important difference in the trends of the mortality rates with time. Thus, in each age group the mortality from the acute leukemias increased between 1945 and 1957, whereas the mortality from the chronic leukemias, with the exception of chronic myeloid leukemia in men, increased during the period of observation only in the older age-groups. At these ages the mortality increased for all types of leukemia in both sexes, but the increase in chronic lymphatic leukemia in men was outstanding. The observed increase in the age-specific death rates of acute leukemia at ages under 60 years was largely real and due to increasing exposure of the population to leukemogenic factors in the environment, but most of the increase in the death rate from the chronic leukemias was due to their better recognition consequent upon improved medical care for the elderly.

The extent to which exposure to ionizing radiation may be responsible for at least some of the recorded increase in leukemia mortality has been the subject of controversy. It is important to note the evidence that radiation exposure has been associated with an increase in the acute leukemias more often than with an increase in chronic myeloid leukemia, and not at all with an increase in chronic lymphatic leukemia. The extent to which the increases in the national mortality rate from acute leukemia may be related to increases in our artificial radiation background can be adequately assessed only with greater knowledge of the basic mechanisms of cancer induction and of the relationship between radiation dose and incidence.

Multiple Myeloma: Two Cases with Unusual Clinical Symptoms. E. A. Ramírez. Bol. Asoc. méd. Puerto Rico 51:1-11 (Jan.) 1959 (In English) [Santurce, P. R.].

Eleven patients with multiple myeloma were observed at the Faculty of Medicine of the University of Puerto Rico over a period of 12 years. Three of these patients showed no specific bone lesions roentgenologically; in 3 others the symptoms were not those of multiple myeloma; and 5 did not have Bence-Jones proteinuria. The cases of 2 men, 59 and 80 years old, are reported. The finding of Bence-Jones protein was not demonstrated in the urine of either patient. The younger patient complained of illness of 2 weeks' duration, consisting of respiratory disorders, profuse perspiration at night, and moderate fever. On hospitalization he was dyspneic and cyanotic and had moderate fever. A Bucky chest roentgenogram showed enlargement of the heart, left-sided pleurisy, and bone lesions of the myelomatous type on the lower ribs, the clavicles, and the scapulas. Fluid obtained by a pericardiocentesis was serohemorrhagic. A chest roentgenogram after the pericardiocentesis showed a parietal pericardial thickness of 4 mm. The cardiac pulsations were almost unnoticeable on fluoroscopy. The electrocardiogram showed changes characteristic of pericarditis. The treatment consisted of the administration of digitalis, diuretics, and urethan. There was a slow regression of the clinical symptoms. The cardiac pulsations observed on fluoroscopy improved. The patient was discharged in satisfactory condition 5 months after hospitalization. Recurrences appeared, however, at intervals of 3 months, showing constant progression of the disease which did not respond to urethan treatment, and the patient died a year and a half after the appearance of the first symptoms. Autopsy showed multiple myelomatous lesions of almost all the bones and severe myelomatous lesions of the pleura and the pericardium. There was no valvular disease, atherosclerosis of the coronary arteries, lesions of rheumatic fever, or tuberculosis of the lungs or the pericardium.

The older patient complained of a large tumor which appeared on the right side of the frontoparietal region 3 months before consultation. Needle aspiration biopsy of the tumor showed multiple myeloma. Myeloma cells were also found in the bone marrow. The roentgenogram of the skull showed a defect corresponding to the lesion and numerous small defects of multiple myeloma. The treatment consisted of the administration of urethan, up to a total dose of 44 Gm., within a period of 3 weeks. A sudden marked regression of the tumor occurred several days after withdrawal of the drug, and this regression lasted 6 months. Recurrences, followed by regression of the tumor under the effect of urethan therapy, occurred 4 times at short intervals. Each regression lasted 2 to 4 weeks after discontinuation of the treatment, the patient receiving a total dose of 191 Gm. of urethan. In contrast to the good clinical response to urethan, constant radiologic progression of the lesion was observed. The patient died 2½ years after the appearance of the first symptoms. No autopsy was permitted.

In the 2 cases reported, the advanced period of the illness was marked by the development of acute anemia, disturbances of the electrolytes, mental confusion, and hemorrhages. The author believes that cases of multiple myeloma exclusively located on the pleura and on the pericardium have not previously been reported in the literature, his being the first to be reported. He directs attention to the good, but transient, effects of urethan on the tumor in the second patient, this medicament causing regression of the tumor several times in the presence of progression of the disease.

Immediate and Late Results in Radiophosphorus Therapy of Erythremia. E. D. Duboviy and M. A. Yasinovsky. Klin. med. 37:30-37 (April) 1959 (In Russian) [Moscow].

The authors report on 53 patients with erythremia treated with radiophosphorus (P^{32}). Good results were obtained in 48 of the 53 patients. In the majority of the cases, most pronounced clinical and hematological effects were obtained 3 to 5 months after the course of treatment with P^{32}. Relapses took place in less than 2 years in most of the patients. Repeated institution of the treatment usually produced a good effect. In the majority of the patients remission lasted 2 or 3 years, and in some of them 4 or 5 years.

SURGERY

Surgical Considerations of Occlusive Disease of Innominate, Carotid, Subclavian, and Vertebral Arteries. M. E. DeBakey, E. S. Crawford, D. A. Cooley and G. C. Morris Jr. Ann. Surg. 149:690-710 (May) 1959 [Philadelphia].

The authors performed arteriographic studies on 174 patients with manifestations of arterial insufficiency of the cerebrum and upper extremities. These studies revealed the presence of extracranial arterial occlusion in 73 patients (42%), 63 of them being subjected to operation. In this latter group of patients a total of 115 extracranial lesions occurred; these were located in the internal carotid, vertebral, innominate, common carotid, and subclavian arteries, single lesions being present in 31 patients and multiple lesions in 32. Eighty-eight lesions were explored surgically, and 75 obstructive lesions, occurring in 53 patients, were found to be segmental in nature and amenable to restorative operation. The reported observations are concerned with these 53 patients. The remaining patients had extensive complete occlusion of the internal carotid or vertebral arteries, and in view of the duration of the occlusion the lesions were not considered operable.

The proximal forms of the disease were evident clinically by the manifestations of arterial insufficiency of the cerebrum and upper extremities. The distal occlusions were manifested by cerebral arterial insufficiency. Due to the limitations of accurate localization of the lesions on clinical grounds, all the patients were subjected to arteriographic studies. Lesions occurring in the great vessels arising from the aortic arch were operable regardless of the location and extent of the occlusion. Incomplete occlusions of the internal carotid and vertebral arteries were similarly amenable to operation. Complete occlusions of the latter vessels were rarely operable unless explored soon after onset of symptoms. Surgical treatment was directed toward restoration of normal circulation. To achieve this objective, 2 types of procedures were employed, namely, endarterectomy and end-to-side bypass graft. Endarterectomy was employed in the treatment of well-localized lesions, and the more extensive occlusions were bypassed by means of a suitable arterial substitute. Endarterectomy was performed on 37 lesions, and graft bypass was employed in the treatment of 38 lesions. A pulsatile circulation was restored in the treatment of 72 of these 75 lesions. Circulation was restored in all patients with lesions involving the great vessels arising from the aortic arch, in 97% of those with operable lesions of the internal carotid artery, and in 60% of those with occlusions of the vertebral artery.

Severe cerebral arterial insufficiency manifested by coma and paralysis was present before the operation in 3 patients, and although circulation was restored in one or more of the occluded vessels, death resulted from irreversible ischemic damage of the brain. Two patients died of myocardial infarction after the operation, and one died of hemorrhage. All the patients with lesions of the great vessels obtained complete relief from their symptoms, and most of those with lesions of the internal carotid and vertebral arteries were either relieved or improved. These patients have been followed for periods of up to 5 years, and the success achieved by the operation has been well maintained.

Surgical Treatment of Occlusive Disease of the Carotid Artery. H. T. Bahnson, F. C. Spencer and J. K. Quattlebaum Jr. Ann. Surg. 149:711-720 (May) 1959 [Philadelphia].

The authors report on 9 women and 13 men, between the ages of 22 and 78 years, who underwent surgical exploration for occlusive disease of the carotid arteries. The commonest site of the occlusive lesions was near the bifurcation of the common carotid artery, this site being present in 20 of the 22 patients. Partial obstruction was present in 13 and complete obstruction in 7 of the 20 patients with upper carotid obstruction. The origin of the innominate or the left common carotid artery from the aorta and the adjacent portions of the carotid or innominate arteries or the aorta were involved in the remaining 2 patients with lower carotid obstruction. Endarterectomy was the procedure of choice in treating the patients with upper carotid obstruction, and bypass or direct replacement therapy was the preferred method for obstruction near the origin of the vessels from the aorta. In the usual operation performed expeditiously, no measure to support the distal circulation is necessary during the required temporary carotid occlusion. When the obstruction is unusual or extensive, a temporary bypass may be used to allow a longer period of safe operative occlusion.

The observations made in treating these 22 patients justify the following conclusions. A remediable narrowing of the carotid arterial system may be present in patients who have sudden or episodic unilateral motor or sensory disturbances, syncope, ocular symptoms, or speech disorders. A single symptom complex does not exist. Unilateral blindness and contralateral hemiplegia, described formerly as a hallmark of carotid occlusion, are present in only a small number of patients. The variations in symptoms reflect variations in collateral circulation and involvement of other vessels and emphasize the need for carotid arteriography in evaluation of these patients. Such an obstruction must be sought at both the origin of the vessels from the aorta and the bifurcation of the common carotid artery in the neck. The most favorable cases are those in which there is a history of transient attacks of neurological symptoms without significant continuing neurological deficit and in which an area of localized obstruction can be revealed. When symptoms are continuous and the neurological deficit is marked, benefit from surgical treatment is less likely. Of the 13 patients with partial upper carotid obstruction, 1 obtained complete relief, 7 were improved, and 5 were therapeutic failures, 2 of them dying within 24 hours and 1 week, respectively, after the operation. Of the 7 patients with complete upper carotid obstruction, 2 died, and 5 were therapeutic failures. Complete occlusion of the internal carotid artery will rarely be treated successfully unless the occlusion is of very brief duration. The 2 patients with lower carotid obstruction made a complete recovery.

Surgery of Subpleural Blebs: Indications and Contraindications. F. Feraru and C. S. Morrow. Am. Rev. Tuberc. 79:577-590 (May) 1959 [New York].

The authors report on 7 men, between the ages of 22 and 68 years, 3 of whom were operated on for subpleural blebs, while 4 presented varied contraindications to surgical intervention. The patients were studied by determination of the vital capacity and maximal breathing capacity with the aid of a 9-liter Collin's respirometer, a modification of the Benedict-Roth metabolism apparatus. Bronchospirometry was performed with the aid of a flexible double-lumen catheter. All the patients considered for surgical intervention were studied by bronchoscopy and bronchography unless contraindicated by extreme pulmonary insufficiency. Angiocardiography, which was performed on one patient, revealed avascularity of the bullous area.

Operation was performed with the aid of endotracheal anesthesia in as simple a manner as possible to provide minimal risk. The pleural cavity was entered through the 4th intercostal space anteriorly. All large blebs were unroofed. The parietal pleura was rubbed lightly with dry gauze to provoke adhesive reaction. It is believed that the operation should be conservative of lung tissue. Only giant blebs are considered for removal. They must be big enough to cause demonstrable compression of adjacent lung tissue. The blebs must be the major factor in the altered respiratory efficiency. Coexistent diffuse emphysema may also be present but is probably part of the same process. Any other added pulmonary disease should raise doubt of the primary importance of the blebs. Further studies, particularly of lung compliance, are indicated. The operation is recommended both as a prophylactic and as a therapeutic measure to improve pulmonary function.

A Case of Pericardial Cyst. G. Besa. Fracastoro 52:131-138 (March-April) 1959 (In Italian) [Verona, Italy].

The author reports on a 32-year-old man with a pericardial cyst which was treated surgically. A roentgenologic examination made when the patient was 24 years old showed a "double curve" of the left ventricle. Five years before operation he suffered occasional transitory pain in the precordium on exertion. Just prior to operation he had severe precardial pain radiating into the left shoulder, but these symptoms gradually disappeared in 3 days. Neither fever nor cough was present. A paracardiac shadow at the base of the left lung was noticed on roentgenologic examination of the thorax. The patient was subjected to posterolateral thoracotomy on the left, with partial resection of the 6th rib. An irregular oval swelling, the size of the head of a fully developed fetus, covered by the mediastinal pleura, was found adjacent to the pericardium. The anterior pole of the mass reached the anterior phrenicocostal angle. The diaphragmatic surface of the lower lobe of the lung adhered loosely to the parapericardial formation. After the lung had been completely freed and the phrenic nerve reflected, the mass was easily removed. The mass consisted of a voluminous grayish-yellow cyst, with thin, transparent walls, and was filled with fluid; a thin pedicle connected it with the pericardium. It was oval and had a translucid surface, measured 13 by 8 by 7 cm., and weighed 420 Gm. The author believes that the absence of clinical symptoms is not a necessary characteristic of a pericardial cyst and that the presence of clinical symptoms depends on the size and development of the neoformation.

An Analysis of Rupture of Thoracic Aneurysms Subsequent to Abdominal Aneurysmectomy. E. Senderoff, L. Blum and I. D. Baronofsky. Surg. Gynec. & Obst. 108:567-574 (May) 1959 [Chicago].

Although aneurysmal dilatation of the aorta is usually restricted to one particular location, the underlying pathological process of atherosclerosis, calcium deposition, loss of elasticity, and dilatation of the vessel wall occurs throughout the aorta, and in some cases multiple aneurysms are present. The authors present a clinical and pathological analysis of 2 cases of multiple aortic aneurysms. In both patients, men aged 55 and 72 years, respectively, the lowermost aneurysm was treated first, with fatal rupture of the most proximal aneurysm occurring relatively soon afterward. While one cannot definitely state that these events occurred as cause and effect, the supposition is a strong one.

In the surgical repair of abdominal aortic aneurysms, the aorta proximal to the aneurysm is completely occluded for a significant period of time. The authors cite studies carried out by others which showed that occlusion of the aorta in man affects the blood pressure proximal and distal to the point of occlusion. While the normal aorta with good elastic fibers in the media is able to withstand changes in blood pressure, the diseased aorta may not be able to withstand increased pressure. As seen in the cases presented, the thin walls of the thoracic aneurysms contain atheromatous plaques, areas of degeneration and necrosis, and fragmentation and depletion of the elastic fibers. If the increased intra-aortic blood pressure, resultant from aortic occlusion during surgical repair of the abdominal aneurysm, exerts a stress on the proximal vessel wall causing further fragmentation of the elastica, cracking of the atheromatous plaques, or beginning dissection of the necrotic wall, then the repair of the distal aneurysm may become an added factor in initiating the onset of the rupture of the proximal aneurysm. It is suggested that, in the event of staged repair of multiple aortic aneurysms, the most proximal aneurysm should be repaired first.

Rehabilitation and Work Capacity after Pulmonary Resection (Results 2 to 7 Years after the Operation in 291 Patients with Pulmonary Tuberculosis). F. W. Gierhake. Beitr. Klin. Tuberk. 120:135-149 (no. 2) 1959 (In German) [Berlin].

The author reports on 291 patients with pulmonary tuberculosis, who underwent pulmonary resection in the surgical clinic of the University of Giessen, Germany, between 1951 and 1955. Two to 7 years after the operation 252 (86.6%) of the 291 patients were living and were free of recurrence of tuberculosis. These 252 persons were examined concerning their work capacity. According to the findings, 215 (85.3%) were working; 23 (9.1%) were invalids, but they had a functionally satisfactory result and were able to do light work; 7 (2.8%) were still unemployed but were able to work; 3 (1.2%) were not able to work; and 4 (1.6%) were still being treated for postoperative complications. The reduced pulmonary function in the patients who did not work had already been essentially present before the pulmonary resection, or it depended on postoperative complications. A cause-and-effect relationship was present between these complications and the preceding collapse therapy and the long duration of the disease, but not between the postoperative complications and the resection. The rare recurrences, the slight operative risk in unfavorable cases, and the favorable functional results of pulmonary resection justify the recommendation to perform it on all patients in whom a cure cannot be obtained with conservative treatment and chemotherapy.

Carcinoma of the Stomach and Blood Group. H. W. Schreiber, W. M. Bartsch and W. Dauer. Beitr. klin. Chir. 198:193-205 (no. 2) 1959 (In German) [Munich, Germany].

The authors survey the literature concerning the correlation between blood group and disease. Whereas some investigators reported that patients with a certain blood group showed a greater tendency for such diseases as anemia, tuberculosis, diabetes, and various types of malignancies, others were unable to confirm these correlations. The authors had an opportunity to review the records of 311 patients with carcinoma of the stomach, who were treated at the surgical clinic of the University of Bonn during the decade from 1948 to 1957. These patients represented a selected group insofar as only those were included for whom the blood group was known and for whom the diagnosis had been histologically verified. The percental distribution of the blood groups of these patients and a comparison with the results on blood group distribution in gastric cancer obtained by another investigator are recorded in a table. The authors also present a critical analysis of the data on which the literature reports as well as their own studies are based. They conclude that there is no association between a certain blood group and carcinoma of the stomach, and that there is no proof of the so-called interior relationship between blood group and cancer of the stomach.

Hepatocerebral Intoxication as Complication After Portacaval Shunt Operation. J. Dortenmann and O. Müller. Beitr. klin. Chir. 198:206-214 (no. 2) 1959 (In German) [Munich, Germany].

The authors present the history of a 42-year-old man with hepatic cirrhosis, who 12 years before had undergone omentopexy because of severe ascites. After this operation ascites subsided, and the patient remained comparatively well until December, 1957, when he was again hospitalized because of the recurrence of ascites. After a severe hemorrhoidal hemorrhage, and because of a threat of bleeding from esophageal varices, a portacaval end-to-side anastomosis was made. Seven days after the operation the patient became comatose, and neurological examination revealed hyperreflexia of the right side of the body, a clonus of the right leg, an increase in tonus of the entire skeletal musculature, and compulsive gaze. Hepatic coma was thought of, but since fetor hepaticus, Kussmaul's air hunger, and increase in pulse frequency were absent, and since the neurological symptoms likewise did not fit in with the picture of hepatic coma, this diagnosis had to be rejected; hypokalemic coma could also be ruled out. The condition was diagnosed as hepatocerebral intoxication, in which loss of consciousness and clonic spasms are the chief symptoms.

The cerebral intoxication is caused by the absorption of ammonia (derived from the breakdown of proteins in the intestine) directly into the systemic circulation because of circumvention of the liver. Treatment consists in avoiding foods high in protein, particularly meats, and, in case of bleeding into the gastrointestinal tract (esophageal varices), stomach and intestine should be evacuated. The intestinal flora favoring protein decomposition should be suppressed in order to reduce the ammonia content of the blood. Observations suggest that the hepatocerebral intoxication is not so much a pathophysiological problem of the liver as it is the result of changes in the portacaval outflow system, and so the term "portacaval short-circuit syndrome" has been applied to it. Possibly the mode of anastomosis (end-to-side) is partly responsible, but this type of anastomosis has the advantage of being technically simpler and of being more secure against thrombotic occlusion than the side-to-side anastomosis.

PEDIATRICS

The Anomalous Origin of the Left Coronary Artery from the Pulmonary Artery. J. D. Keith. Brit. Heart J. 21:149-161 (April) 1959 [London].

The author studied 10 children with anomalous origin of the left coronary artery from the pulmonary artery at the Hospital for Sick Children in Toronto. Fifty cases of this congenital heart defect were collected from the literature. In relating the condition to the child population in the Toronto Heart Registry, it appeared once among 300,000 children. This rare defect usually causes death within the first year of life, and at autopsy it is characterized by an enlarged, somewhat thin-walled left ventricle and a patchy fibrosis in the part of the left ventricle supplied by the anomalous coronary artery. The abnormal change would appear to be related more to the inadequate blood supply than to the oxygen content of the blood delivered. The diagnosis should be suspected in an infant in the first year of life in whom signs of heart failure develop, who has an enlarged heart, and from whom an electrocardiogram is obtained with evidence of myocardial fibrosis in the anterior portion of the left ventricle. The diagnosis may be largely confirmed by an aortogram carried out with the catheter just above the aortic valve. This will reveal filling of the right coronary artery from the aorta but will not reveal any filling of the left coronary artery. Adequate surgery has not yet been evolved, but it would appear possible that an anastomosis might be completed between a segment of the aorta at the site of the left coronary artery and a systemic artery. If this were carried out early enough before advanced myocardial change had occurred, normal heart function might result.

A New Simple Test Paper for Mass Detection of Phenylketonuria. J. Wortis and A. M. Giancotti. Am. J. Pub. Health 49:463-464 (April) 1959 [Albany, N. Y.].

Since phenylketonuria, a metabolic anomaly associated with mental retardation, can now often be beneficially treated with a phenylalanine-free diet, it has become desirable to detect its presence as early as possible, for the diet loses its efficacy as the child grows older. Test papers for the detection of phenylketonuria were developed by 2 pharmaceutical manufacturers. Small strips of the prepared paper are used by immersion in a fresh urine specimen or by simple pressure against a wet diaper. The studies reported were carried out with one of the test papers, in which the presence of phenylpyruvic acid in the urine produces a color change from the original yellowish white to a blue of varying density, depending on the amount of phenylpyruvic acid present.

The test paper was distributed by mail or handed to parents in a total of 1,600 families with retarded children. Six hundred of these children had been treated in the clinic, and 1,000 additional cases were contacted through the mailing lists of the New York Association for the Help of Retarded Children. The test paper was accompanied by an explanatory letter. This method of screening has provided fairly complete coverage for the children most likely to be helped; its chief advantage is that it can be carried out by technically untrained people at very little cost. The authors recommend that the test be widely used for similar surveys of large populations of retarded children. Since phenylketonuria may not be detectable during the first weeks of life, it should be adopted by pediatricians as a routine test for infants at least one month of age.

DERMATOLOGY

Alopecia Mucinosa. W. C. Johnson, R. S. Higdon and E. B. Helwig. A. M. A. Arch. Dermat. 79:395-406 (April) 1959 [Chicago].

Alopecia mucinosa is a dermatosis described by Pinkus in 1957. Clinically it appears as single or multiple, slightly erythematous, raised plaques, associated with loss of hair in the sites involved. Pathologically, the changes are in the pilosebaceous apparatus. After Pinkus presented his paper at the International Congress of Dermatology at Stockholm, Szodoray, of Budapest, said he had published a similar case with Lehner, in 1939, and he also referred to a case published by Kreibich, in 1926. Kreibich described a generalized patchy eruption in a youth, under the title "Mucin in a Skin Disease." The distinctive histopathological feature was the presence of cystic spaces and mucin within the pilosebaceous follicle. There was a perifollicular infiltrate with numerous lymphocytes and occasionally some mucinous material.

A review of cases previously diagnosed as alopecia, follicular hyperkeratosis, folliculitis, ichthyosis, keratosis pilaris, parapsoriasis, phrynoderma, and pityriasis rubra pilaris disclosed 8 examples of alopecia mucinosa at the Armed Forces Institute of Pathology. Of these, 1 case had previously been recorded as acute folliculitis; 2, as consistent with pityriasis rubra pilaris; and 5, as chronic folliculitis. Each of the 8 patients answered a questionnaire concerning the course of his disease and present status. The period of follow-up ranged from 3 to 13½ years from the date of onset. Paraffin-embedded tissue from the 8 patients was available for study and was examined with the aid of several staining and histochemical techniques. The histories of the patients are presented. The authors are of the opinion that the pathogenesis of alopecia mucinosa as a clinical and pathological entity is primarily a change in the epithelial cells within the pilosebaceous follicle, which results in the accumulation of mucin, inflammation in the corium being secondary. The mucinous material is an acid mucopolysaccharide and consists of hyaluronic acid or chondroitin sulfate or both. Pinkus suggested that the disease may be infectious, perhaps of viral etiology. The authors interpret the lack of evidence of contagion, the chronicity and recurrent nature of the eruption, and the histochemical similarity of the mucin to that seen in myxedema to indicate a metabolic process.

Idiopathic Lethal Granulomas of the Midline Facial **Tissues.** B. R. Alexander. A. M. A. Arch. Dermat. 79:390-394 (April) 1959 [Chicago].

The case of idiopathic lethal granuloma presented concerned a 48-year-old woman, in whom sprue had been diagnosed in April, 1956. When she returned in September, 1956, she complained of a sore throat, which had been treated unsuccessfully with penicillin and sulfonamides, of small painful nodules on her lower extremities, and of sinusitis and nasal "stuffiness" of several years' duration. The pharynx and soft palate were injected, and the tonsils were enlarged. There were tender, painful nodules on the lower extremities. Histopathological studies of tissue taken from one of these nodules showed changes consistent with periarteritis nodosa. The patient improved in the hospital without specific therapy and remained fairly well for a while. Six months later, though, she was readmitted with an ulcer at the junction of the soft and the hard palates of 8 weeks' duration. Roentgenograms of the hard palate showed a penetrating lesion into the floor of the right nostril. Fungous cultures from ulcer material were negative; bacterial cultures showed a mixture of Neisseria organisms and viridans streptococci. Histopathological studies showed necrotic granulation tissue.

In spite of broad-spectrum antibiotics and general supporting therapy, the ulcerative and necrotic lesion on the palate became more extensive and painful. A clinical diagnosis of idiopathic lethal granuloma of the midline facial tissues was now made, and the patient was given prednisolone. Within a week there was moderate improvement of the ulcer on the palate. Two weeks later swelling was noted on the right side of the nose and over the maxilla on the right. Transillumination revealed a shadow in the region of the right maxillary sinus, and it was assumed that the granulomatous process had extended. In spite of an increase in the dosage of prednisolone, the swelling progressed. There was loss of weight, weakness, cachexia, and progression of the granulomatous and ulcerative lesion. Terminally the patient's vision became blurred, the eyes bulged, the face was grossly deformed, and there was a serosanguineous discharge from the eyes and the nose. Death came 10 months after the onset of the pharyngitis.

The author reviews the literature and points out that malignant granulomas of the midline facial tissues are associated with chronic sinusitis, psychic trauma, upper respiratory infections, or sulfonamide therapy. It is hypothesized that subsequently a relative adrenal insufficiency develops and, because of a lack of the "antagonistic" effect of the adrenal cortical hormones, a local tissue allergy (Arthus' phenomenon) or periarteritis nodosa develops. The necrotic, ulcerative, and granulomatous processes follow. Because of the adrenal insufficiency, corticotropin (ACTH) and cortisone have been used for palliation. In spite of the patient's symptomatic improvement on these drugs, the malignant process continues, with a rather rapid termination of life.

The Relationship of Systemic Lupus Erythematosus and Discoid Lupus Erythematosus: A Clinical and Hematological Study. A. Scott and E. G. Rees. A. M. A. Arch. Dermat. 79:422-435 (April) 1959 [Chicago].

There are 2 main divisions of opinion with regard to the relation of discoid lupus erythematosus, originally described as a purely cutaneous disorder, to the systemic illness. While most clinicians feel that the 2 disorders are one and the same disease, merely representing the 2 extremes of one pathological process, there are a few dissenters who question this theory because of the large number of patients with cutaneous lesions who have been cured and have remained so without any evidence of involvement in other systems. The discussion received a fresh impetus by the demonstrations of Hargraves, Richmond, and Morton, in 1948, of the polymorphonuclear phagocyte with its basophilic inclusion body that has been given the name of "L. E. cell."

The authors present observations on 118 patients with lupus erythematosus, either systemic or discoid cutaneous, who have been clinically diagnosed as such and have been followed in St. Bartholomew's Hospital, London, during the past 8 years. These patients have been rechecked at least twice yearly on the basis of both clinical examination and laboratory investigation. The aim was (1) to classify these cases into groups on the basis of their clinical features, (2) to review these clinical features briefly, (3) to study the natural course of the disease in the several groups, (4) to consider the features which distinguish the cutaneous lesions of discoid lupus erythematosus from those observed in systemic lupus erythematosus, (5) to investigate the incidence of the L. E. phenomenon in the groups and to consider the value and import of this sign in the development and prognosis of the 2 diseases, and (6) on the basis of these studies to determine the relation between systemic and discoid lupus erythematosus.

One hundred two patients in this series had discoid lupus erythematosus. A grouping of these patients was made on the basis of clinical history, physical examination, and laboratory investigation. The L. E. phenomenon was studied in all of them as well as in a large control group. The results of the L. E. tests closely paralleled the clinical appraisal. By means of strict criteria for diagnosing systemic lupus erythematosus, the authors were able to make the diagnosis in only 12% of the patients with discoid lupus erythematosus. This proportion would be the maximum number, since inclusion of the total number of patients with discoid lupus erythematosus would reduce that percentage to 5%. No final conclusions could be made regarding the pathogenetic relationship of the 2 disorders.

Elastosis Perforans Serpiginosa: Elastoma Intrapapillare Perforans Verruciforme or Keratosis Follicularis Serpiginosa (Clinical and Histological Study of First Cases in the United States). J. M. Hitch and H. Z. Lund. A. M. A. Arch. Dermat. 79:407-421 (April) 1959 [Chicago].

The authors present the histories of 5 patients with elastosis perforans serpiginosa, which they believe to be the first cases of this skin lesion reported in the United States. They summarize salient features of 10 other cases observed in countries of Europe and Africa and reported under various names in the literature since 1945. All but 2 of the 15 patients were males. The lesions, usually on the sides of the neck, consisted of discrete papules which were firm, bright-red to saffron, with abrupt sides, and usually in an arciform arrangement. The papules had a keratotic cap which was firmly adherent and, on forceful dislodgment, left a bleeding crater. The skin of the central cleared region was hypopigmented, slightly rigid, and the site of prominent follicular orifices. Hair growth was not interrupted in either the active papules or the cleared central portion of the annular lesions. Specimens for histological examination were available.

The verrucous nature of the lesion is explained by marked acanthosis, with the formation of penetrating epidermal pegs and reactive proliferation of connective tissue in the papillary and subpapillary layers. The pathognomonic feature of the lesion is a peculiar proliferation of fibers resembling elastica. These often penetrate into the epithelium of rete ridges and the margins of follicles and sweat glands, and here and there open a channel to the cutaneous surface. The authors were unable to demonstrate intrafollicular penetration, but it is possible that sweat ducts are disrupted. The mechanism of penetration is not understood. It may be that the replacement of normal fine elastic fibers by the coarse and abnormal fibers around adnexal structures or at the dermoepidermal junction causes local physical changes leading to dermoepidermal separation or disruption of the margins of sweat ducts and hair follicles. The coarse fibers then penetrate the epithelium and lead to a reactive acanthosis. Perforation to the surface may be through the epidermal portion of the sweat ducts, but this has not been proved. Healing takes place by degeneration and phagocytosis of at least part of the proliferated elastic tissue, and there is a variable degree of ingrowth of fibrous tissue between the epidermis and the stratum reticularis. The fibrous tissue is largely collagenous, but interestingly it also contains some moderately fine elastic fibers.

The authors endorse the designation of "elastosis perforans serpiginosa," offered by Dammert and Putkoven, over those previously proposed by Lutz and Gruneberg, which they consider inaccurate. Though they are in general agreement with Miescher in regard to the histopathological picture, they find that the elastosis is not primarily or necessarily "intrapapillare," and surely it is not a tumor, as might be suggested by the suffix "oma."

OTOLARYNGOLOGY

Neomycin Ototoxicity. G. J. Greenwood. A. M. A. Arch. Otolaryng. 69:390-397 (April) 1959 [Chicago].

The author suggests some precautions in the systemic use of neomycin sulfate that may help to obviate ototoxicity. This report presents 20 cases of ototoxicity collected from the literature and an added case which corroborates the findings in the collected cases. To this end attention is directed to reports of the synergistic antibiotic-vitamin pharmacological action. Isotopically tagged chelated metals might be microradiographically utilized in an effort to uncover why specific drugs affinitively attack certain cellular constituents of the labyrinth.

The Ototoxicity of Kanamycin Sulfate in the Presence of Compromised Renal Function. R. F. Naunton and P. H. Ward. A. M. A. Arch. Otolaryng. 69:398-399 (April) 1959 [Chicago].

The authors report on 2 men, aged 40 and 48 years, in whom the hearing mechanism was severely damaged after the administration of relatively small doses of kanamycin sulfate (Kantrex). One of the 2 men had been given 14 Gm. over a 7-day period, and the other a total dosage of 5 Gm.

over a 5-day period. Each of the 2 patients had had a previous nephrectomy and was thus in a state of compromised renal function despite adequate urinary output. It is emphasized that new drugs with ototoxic potential should be used with the greatest caution, particularly in patients with questionable renal function.

Unusual Foreign Bodies in the Upper Respiratory Tract: Ten Cases of Leeches. C. A. Falidas. A. M. A. Arch. Otolaryng. 69:416-418 (April) 1959 [Chicago].

The leech is a very rare foreign body that can cause anxiety and other disturbances in the human host. The author reports 10 patients in whom leeches were found in the upper respiratory tract. These patients lived in a low land in the center of Greece where leeches are found in springs and brooks. During the summer season they, like others from their village, worked in the fields, where they used infested water. The entrance of a leech into the human system is often but a casual incident; however, early medical intervention is necessary to prevent a serious loss of blood and to spare the patient much anxiety. The construction of modern works for proper water supply can deliver a population from the threat of leeches. Appropriate education as regards the danger of drinking water without prior filtration may serve as a temporary preventive measure.

Bronchography in Carcinoma of the Lung. E. Huizinga. Pract. oto-rhino-laryng. 21:81-90 (March) 1959 (In English) [Basel, Switzerland].

The author studied 250 patients with carcinoma of the lung on whom bronchography was performed. In 179 of the 250 patients the bronchograms revealed an obstruction of a bronchus; in 33, a stenosis; in 4, a displacement of a bronchus; and in 1, a large cavity. Thirty-three bronchograms were negative. Although no abnormalities may be seen, the bronchograms are significant. The localization in a certain segment becomes clear, indicating in which bronchus Clerf's method of washing should be performed for the cytological examination. An anomaly in a large bronchus can easily be seen with the bronchoscope, but through bronchography more than one anomaly can be detected. In about 15% of the patients in this series bronchography revealed changes caused by metastases in the hilar glands, mostly stenosis of the main bronchus or of the lower part of the trachea, besides the anomaly of the primary tumor. These abnormalities are demonstrable by bronchoscopy and sectional radiography, but bronchography gives a better over-all picture.

Bronchography makes a "directed" bronchoscopy feasible. According to the indications obtained from the bronchogram, a certain branch is focused, and from this branch curetting is done blindly or a biopsy is performed with very fine forceps. Carcinoma of the lung nearly always arises from the mucosa of a larger bronchus. This is the reason why the obstruction of a certain bronchus is so often revealed by bronchography. However, the obstruction is often caused by pressure from the outside or by tissue in the lumen. Therefore, the bronchoscopist ought not to draw too far-reaching conclusions from the changes in the lumen seen with bronchoscopy. Sometimes a perfectly smooth surface in the bronchus is observed in cases of carcinoma as well as in cases of tuberculosis. An adenoma may be lobed, while with a common infection the mucous membrane may be granulated. Bronchograms performed on the 250 patients in this series revealed that the obstruction seen in 179 cases had a smooth outline in 99 and an irregular outline in 80, whereas the stenosis observed in 33 cases showed an irregular outline in 22 and a smooth outline in 11. In 36 patients the obstruction was located at the beginning of the bronchus and did not show on the bronchogram. In some cases the bronchus was missing on the bronchogram as the result of a compression, but often there were other causes. The completely smooth outline of the obstruction, plus the fact that the part of the lung concerned had diminished while other parts had increased in size, resulted in a picture which remained difficult to interpret. Clinical diagnosis on the basis of bronchograms should be established with the utmost consideration. Bronchography is a valuable contribution to bronchoscopy and lung surgery in that it enables disease conditions to be localized accurately, and indications regarding involvement of the main bronchi are obtained.

THERAPEUTICS

Crystalline Pancreatic Desoxyribonuclease as an Adjunct to the Treatment of Pneumococcal Meningitis. A. J. Johnson, J. H. Ayvazian and W. S. Tillett. New England J. Med. 260:893-900 (April 30) 1959 [Boston].

The authors report on 25 patients with bacteriologically proved pneumococcic meningitis, 19 (76%) of whom were either less than 4 months old or over 40 years of age, i. e., in age groups in which the prognosis of the disease is unfavorable, and 6 (24%) were between the ages of 4 months and 40 years. The patients were treated with massive doses of penicillin, given intravenously and intramuscularly, and ranging from 12 million to 40 million units per day. Six patients received 5,000 to 10,000 units of penicillin intrathecally on the first day. Crystalline pancreatic desoxyribonuclease was given intrathecally daily to each patient for 2 or 3 consecutive days in doses ranging from 50,000 to one million units per injection. Ten patients were near death on admission. Seven of these, and patients who were thought to have a cerebrospinal fluid block, were given intravenous and intramuscular injections of pancreatic desoxyribonuclease as well; one million units was given as a priming dose intravenously, and 2 million units intramuscularly at the same time. Twelve hours later, 2 million units was given intramuscularly. In this way a blood level of about 30 units was maintained during the entire 24-hour period. The intravenous and intramuscular injections were continued as long as seemed clinically desirable, but were rarely thought to be necessary for more than 2 or 3 days.

Three (12%) of the 25 patients died during the period of observation. Twenty-four (37.5%) of 64 patients with pneumococcic meningitis treated in a similar manner in the same hospital but without administration of pancreatic desoxyribonuclease died between 1951 and 1956. Severe neurological complications occurred in 1 patient, and mild complications in 2. Biochemical studies on the patients' cerebrospinal fluid showed that pancreatic desoxyribonuclease could be recovered from the spinal fluid in moderate amounts for 24 to 48 hours after a single intrathecal injection and that there was a transient increase in acid-soluble desoxyribonucleic acid and a striking decrease in desoxyribonucleoprotein in response to therapy with intrathecally administered pancreatic desoxyribonuclease. There was no evidence of local or systemic toxicity to crystalline pancreatic desoxyribonuclease during the course of this study.

Combination Phenylbutazone-Prednisone Treatment of Arthritis and Bronchial Asthma. M. Giordano, M. Ara and G. Tirri. Minerva med. 50:750-761 (March 14) 1959 (In Italian) [Turin, Italy].

A combined biochemical treatment with phenylbutazone and prednisone, consisting of the oral administration of tablets, each containing 50 mg. of phenylbutazone and 1.25 mg. of prednisone, was given to 73 patients with arthritis or bronchial asthma. The initial dosages varied but did not exceed 8 tablets a day; they were subsequently reduced to 6 or 4 tablets a day. Acute rheumatic disease was present in 18 patients, most of whom had a rheumatic carditis. The treatment produced improvement or disappearance of fever, improvement or complete subsidence of subjective symptoms after 5 to 10 days of treatment, amelioration of the cardiovascular state, and a tendency toward normalcy of the level of C-reactive protein, erythrocyte sedimentation rate, and antistreptolysin titer value. Prednisone alone was substituted for the combined therapy in 2 patients, which change was motivated more by investigative reasons than by the severity of the side-effects.

The combined treatment with phenylbutazone and prednisone produced a rapid regression of fever and joint pain and a fairly rapid disappearance of skin lesions in 2 patients with erythema nodosum. Primary chronic polyarthritis was present in 18 patients. Initial good response with the combined treatment was observed in 14 of these patients, which consisted in decrease of pain and swelling and improvement of articulation. Since only fair results were observed in the remaining 4 patients, prednisone alone, consisting of a daily dose of 25 mg., was subsequently substituted for the combined therapy; superior results with prednisone alone were obtained in one patient. Arthritis was present in 23 patients; the disease had multiple localization in 17 patients, and it was associated with diabetes mellitus in 8. The results of the combined therapy, except in patients with spondyloarthritis, were rapid and good. Patients with diabetes mellitus benefited from and tolerated well the combined therapy. The phenylbutazone-prednisone combination was also given to 12 patients with bronchial asthma; all these patients benefited from the treatment, but better results were observed in those with disease of recent rather than remote origin.

The greatest benefit of the combined treatment with phenylbutazone and prednisone in this series was derived by patients with arthritis. The combination exerted a synergistic action in the sense that relatively the same therapeutic effect in using the drugs singly could be obtained by using the combined preparation, the quantity of prednisone being reduced by one-half and that of phenylbutazone by one-third. This synergistic therapeutic action seemed not to be accompanied by a similar cumulative intensity of side-effects. Edema developed in the lower extremities in 2 patients but disappeared after treatment had been completed. Slight disorders of the gastrointestinal tract developed in 12 patients, compelling discontinuance of the treatment in one.

Abuse of and Dangers in Treatment with Antibiotics: Clinical Viewpoints. H. C. A. Lassen. Nord. med. 61:453-458 (March 19) 1959 (In Danish) [Stockholm].

The commonest mistakes in treatment with antibiotics are as follows: (1) treatment of fever where there is no diagnosis—antibiotics do not have an antipyretic effect; (2) wrong choice of antibiotics; (3) inadequate dosage, not infrequently with resulting masked effect, making exact diagnosis difficult; (4) overdosage and treatment continued too long with danger of toxic effects; (5) application in infections not influenced by antibiotic treatment; (6) inexpedient manner of administration; (7) failure to discontinue the treatment in the presence of complications; (8) failure to change the treatment in spite of the presence of mixed infection; and (9) application of prophylactic treatment except in a few justified cases. Caution in the use of antibiotics would undoubtedly do much to reduce the present-day excessive application and lessen the dangers in treatment with these substances which, rightly applied, are among the most important in the collective therapeutic armamentarium.

Abuse and Dangers in Antibiotic Treatment: Microbiological Viewpoints. H. Ericsson. Nord. med. 61:458-461 (March 19) 1959 (In Swedish) [Stockholm].

The microbiological dangers in antibiotic therapy are summarized as follows: Inadequate therapy becomes ineffective therapy. Antibiotic therapy becomes directly dangerous for the patient when attention is not paid to the action on micro-organisms other than the etiological ones and on parts of the body other than the affected milieu. Antibiotic therapy becomes dangerous for the patient's environment when applied so generally that it contributes to the origin and spread of nosocomial infections. Antibiotic therapy becomes dangerous for antibiotics in that it selects and favors relatively seen bacteria strains which are resistant. Only careful, rational employment of antibiotics can preserve the effectivity and safety of this important group of remedies for the individual patient and for the care of the sick on the whole.

Vitamin K Therapy in Liver Disease: Need for a Reevaluation. F. Steigmann, H. Schrifter, Z. D. Yiotsas and F. Pamukcu. Am. J. Gastroenterol. 31:369-375 (April) 1959 [New York].

The authors investigated the effects of large daily doses of vitamin K in patients with severe liver disease. In a group of 45 patients with cirrhosis, the average initial prothrombin concentration was 34% of normal. Twenty-four hours after the parenteral administration of 72 mg. of vitamin K, the average prothrombin concentration had risen to only 45%, and 48 hours later it had again dropped to 41%. In 22 patients, the hypoprothrombinemia was more marked 48 hours after than 24 hours after the administration of vitamin K. After a 48-hour determination had been made of the supply of prothrombin following the administration of 72 mg. of vitamin K, all the patients were given 50 mg. of vitamin K_1 (phytonadione) administered parenterally. The prothrombin concentration was again determined 24 and 48 hours later, when the average was found to be 49 and 50% respectively.

There are a number of reports in the literature in which excessive amounts of vitamin K have been found to increase the hypoprothrombinemia in patients with severe liver disease. The further depression of the prothrombin level in some patients after parenteral administration of vitamin K suggests that in these cases the liver appears to be functioning at its maximum capacity under the prevailing conditions. The depression may be the result of inadequate production of the substrate with which vitamin K combines, or of abnormal utilization of the substrate with consequent interference with prothrombin formation. The fact that in some patients with liver disease there is either no response or even no depression of the prothrombin level would speak for an exhaustion phenomenon in these particular instances. It has, therefore, been suggested that patients with liver disease and hypoprothrombinemia should be given a small dose of vitamin K and the dose should be repeated only if the prothrombin concentration does not show any further increase. The only manner in which the prothrombin activity can be increased in patients with hypoprothrombinemia who do not respond to vitamin K therapy is by means of transfusion, preferably of whole fresh blood or of frozen plasma.

The Treatment of Nonspecific Ulcerative Colitis by the Topical Administration of the Corticosteroids. M. Patterson and J. McGivney. Gastroenterology 36:480-486 (April) 1959 [Baltimore].

The fact that the corticosteroids have been found useful topically in inflammatory conditions of the skin, eyes, and joint cavities stimulated the authors to study their use in this manner in nonspecific ulcerative colitis. Twenty patients with nonspecific ulcerative colitis were treated. Stools were checked for pathogens, and barium enemas were given. Proctoscopic examinations were given prior to and at frequent intervals during treatment. In addition to the topical steroid therapy, all the patients received bland diets, antispasmodics, sedatives, antidiarrheal agents, blood, or antibiotics when indicated. When the response was good, treatment was continued for from 2 to 4 weeks. When no response was evident at the end of 2 weeks, therapy was discontinued, and if the proctoscopic picture showed exacerbation, therapy was discontinued at once.

The topical steroid therapy was given in 3 different forms: 1. Patients having acute or chronic ulcerative colitis limited to the rectum or rectosigmoid, and without systemic symptoms, were given suppositories containing 10 or 15 mg. of hydrocortisone acetate 3 times a day and at bedtime. It was found that, for optimal effect, the patient should defecate before insertion, so that the rectum would be empty. Women patients were encouraged to urinate before the suppository was inserted as the material was lost during urination. 2. Patients with more acute or chronic disease, who did not respond to suppositories or in whom the process was believed to extend higher into the colon, were given rectal instillations, twice a day, of 50 mg. of hydrocortisone acetate or 10 mg. of prednisone. The tablets were crushed and suspended in 100 ml. of water. The patient was advised to defecate or to flush the rectum with 3 oz. of warm water and to lie down for 30 minutes to an hour after the treatment in the morning and to reserve the evening treatment until bedtime. The instillations were to be self-administered by means of a 3-oz. syringe. 3. In patients in whom a larger area had to be treated, the therapy was given in the hospital once a day with a solution of hydrocortisone sodium succinate (100 or 200 mg.). This solution was added to a 250-ml. or 500-ml. bottle of isotonic sodium chloride solution, and the bottle was attached to an intravenous set. A plastic nasal catheter was then attached to the needle adapter, and the catheter was inserted into the rectum. The solution was started at 20 to 40 drops per minute, but the regulator clamp was so placed that the patient could increase or decrease the flow as long as the urge to defecate was not stimulated. In most patients, the proctoclysis was finished in 1 to 3 hours.

The best results were obtained in patients with early lesions and mild symptoms. The poorest results were observed in patients with long-standing and far-advanced changes, or in those who because of tenesmus or rectal disease could not retain the material. The 78% of over-all good results were no better than with many other forms of therapy in this disease. The impressive features of this therapy were the rapidity with which clinical and sigmoidoscopic remission was obtained, plus the added advantage of minimal absorption of the hormone.

Treatment of the Nephrotic Syndrome with Triamcinolone. L. Hellman, B. Zumoff, A. Minsky, N. Kretchmer and B. Kramer. Pediatrics 23:686-689 (April) 1959 [Springfield, Ill.].

In this report only acute remissions of the nephrotic syndrome after triamcinolone therapy are considered. No conclusions have been drawn regarding the effects of the treatment on the ultimate fate of the 15 children reported. The authors administered triamcinolone (Aristocort) to 4 girls, ranging in age from 1 to 9 years, and to 11 boys, ranging in age from 2 to 5 years, with the nephrotic syndrome. Two of the 15 children had hypertension; one of these had normal concentration of urea nitrogen in the blood and normal urea clearance, whereas the other had azotemia. The remaining 13 children had the nephrotic syndrome in its characteristic form, with all the typical clinical and laboratory findings, but without the stigmata of renal insufficiency. The duration of the nephrotic syndrome in these patients ranged from 15 days to 36 months. Twenty milligrams of triamcinolone was administered orally, in 5 daily doses of 4 mg. each, for 30 to 45 days.

Triamcinolone proved to be a highly effective therapeutic agent. Of the 15 patients treated, 10 had complete remissions and 4 had partial remissions. One of the latter children, who had hypertension without azotemia, received 2 complete courses of triamcinolone; the first course was a failure, but the second produced a partial remission. In another patient with hypertension and azotemia, the treatment was a failure and was discontinued. The typical response to treatment with triamcinolone was an abrupt diuresis, beginning 10 to 12 days after the initiation of treatment and resulting in the complete disappearance of retained fluid in the next 3 or 4 days. During the period of diuresis, the urinary excretion of protein decreased rapidly, and by the time diuresis was complete, the urinary findings were usually within normal limits.

The mere induction of acute remissions, no matter how readily or reproducibly, should not be the chief concern in the therapy of nephrosis. The ultimate prognosis is still pessimistic, despite regimens with currently available steroids. A recent report suggests that the long-term results of steroid therapy in the nephrotic syndrome might be improved by earlier, more intensive, and more prolonged treatment. The authors believe that triamcinolone is a useful steroid for such a program because of its high potency and minimal side-effects. The doses employed did not cause hypertension or retention of sodium.

PATHOLOGY

Capacity of Human Coronary Arteries: A Postmortem Study. F. L. Rodriguez and S. L. Robbins. Circulation 19:570-578 (April) 1959 [New York].

The authors studied the volume capacity of the coronary arteries of 100 hearts which were obtained at autopsy from 57 men and 43 women. Of the 100 hearts, 14 had myocardial infarcts, 7 had chronic valvular disease, 10 had miscellaneous forms of cardiac abnormality, such as bacterial and nonbacterial endocarditis and cardiac mural thrombosis not associated with valvular disease or myocardial infarction, and 69 were normal or had such abnormalities as cardiac hypertrophy and mild coronary or valvular atherosclerosis. The ages of the 100 persons varied from 13 to 95 years. Twenty-eight of them were emaciated, 18 were obese, and 54 were nutritionally normal at the time of death. The amount of Schlesinger's barium sulfate-gelatin injection mass entering the coronary arterial tree under standard conditions was taken as a measure of its capacity. The weight of the heart in the normal and disease state, the cross-sectional dimensions of the main coronary arteries near their origin, and the sex, age, and nutrition of the persons at the time of autopsy were analyzed.

The results showed that the capacity of the coronary arteries increased with the weight of the heart. The relationship between the capacity of the coronary arteries and the cardiac weight was not directly influenced by the presence or absence of cardiac abnormalities other than hypertrophy, or the sex, age, and nutritional status of the person. In persons with cardiac hypertrophy, the increase in the capacity of the coronary arteries did not keep pace with the cardiac mass. In hearts with normal coronary arteries, the capacity of the coronary arterial tree varied in direct proportion to the dimensions of the main coronary arteries near their origins. In hearts with severe coronary atherosclerosis, the over-all capacity of the coronary arterial tree may be maintained despite the diminution in size of its larger components. In hearts from emaciated subjects, the capacity of the coronary arteries was generally reduced in proportion to the loss in cardiac mass.

Primary Pulmonary Alveolar Carcinosis: Carcinoma: So-Called Pulmonary Adenomatosis or Alveolar-Cell Tumor: Review and 12 Personal Cases. E. Roelsen, T. Lund, T. Søndergaard, B. Møller and A. Myschetzky. Ugesk. laeger **121:** 397-407 (March 12) 1959 (In Danish) [Copenhagen].

Pulmonary cancer usually occurs as a primary bronchogenic tumor or as a metastatic process. A third tumor form, the so-called adenomatosis of the lung or alveolar-cell tumor, is a cancer which originates primarily in the lower respiratory tract. Pathologically it is a nosographic entity. Since the first case was reported by Malassez in 1876, more than 200 cases have been published. Presumably cases have been overlooked, both clinically and pathologically, or have been confused with pneumonia. Pulmonary adenomatosis occurs equally often in men and women. It is generally multiple and is localized to one or more lobes and frequently to both lungs. The nodes have a tendency to confluence, by which the diffuse form arises. There is no primary tumor in any other organ. The cases of 12 patients seen by the authors in the course of 8 years in a limited area in Denmark are tabulated; 2 representative cases are described in detail. Eight cases are typical of the diffuse primary pulmonary alveolar carcinosis; 4 cases represent the same histological cancer in its solitary form. The patients with the diffuse form were nonsmokers or nearly so; 3 of the 4 with the solitary form were heavy smokers.

Cough and expectoration are common symptoms for both the diffuse and the solitary forms of pulmonary adenomatosis; dyspnea and cyanosis dominate in the diffuse form. Cough, increasing as the processes progress, is the most conspicuous symptom. The most important criterion clinically is the roentgen-ray picture. The multiple or diffuse form is varied and is difficult to diagnose definitely; in the solitary form there is a solitary infiltrate or round shadow. Invasive growth in lymph tracts is common. The characteristic histological picture shows lung alveoli and alveolar ducts covered with a cylindrical or cubic epithelium which may take on an anaplastic, malignant character. The alveolar structure is preserved. Most important macroscopically are the changes, like those in gray hepatization, seen in cross section. In the series presented, the 8 patients with the multiple form of the disease died within 8 months after the onset of the symptoms. The other 4 patients were operated on, and 2 are living, 5 years and 16 months, respectively, after the operation.

Congenital Absence of the Parathyroid Glands. D. H. Lobdell. A. M. A. Arch. Path. 67:412-415 (April) 1959 [Chicago].

Reports of congenital absence of the parathyroids leading to infantile tetany and death are rare and until now have been confined to the European literature. The case described is that of a child who manifested a parathyroprivic picture throughout his 2 months of life. It is the 5th recorded example of congenital agenesis of the parathyroid glands. This full-term infant, weighing 2,920 Gm. (6½ lb.), was delivered spontaneously from a 24-year-old mother, whose prenatal course was complicated only by anemia. A sibling of the infant was in good health. Neuromuscular hyperirritability was noted at birth. At 39 hours the child was described as a normally developed but "very jumpy" boy, with jerky movements of the extremities when crying or disturbed. Deep tendon reflexes were hyperactive, and periodic clonus was noted. There was no carpopedal spasm or Trousseau's sign. The child had frequent episodes of tetany, manifested by generalized stiffness and shaking, slight cyanosis, and a high-pitched scream. Calcium chloride and calcium gluconate were administered per os, with poor response. Administration of the parathyroid hormone, parathormone, (Ellsworth-Howard test) resulted in more than a twofold increase in urinary phosphate excretion, excluding lack of kidney end-organ response to parathyroid secretion as an etiological factor. Addition of massive doses of vitamin D to the therapeutic regimen resulted in reversal of the abnormal calcium-phosphorus ratio. Oral administration of calcium was discontinued at one month of age, as the infant's neuromuscular hyperirritability diminished. Two tetanic seizures during the 5th week of life were controlled by calcium gluconate.

The child died when 55 days old, and the autopsy findings are described. The author feels that there is little doubt that this is a case of congenital absence of the parathyroid glands. Conditions which can lead to hypocalcemia and tetany, such as chronic intestinal dysfunction, renal insufficiency, and vitamin D deficiency, were not present. The 2-month duration of the symptoms is not compatible with ephemeral "tetany of the newborn." Step sections of the neck organs did not reveal parathyroid tissue. The thymus, which develops with the parathyroids from branchial pouches III and IV, was absent. In addition, 2 other congenital malformations, agenesis of the thyroid isthmus and an anomalous vascular ring, were found.

BOOK REVIEWS

Headache: Diagnosis and Treatment. By Arnold P. Friedman, M.D., Associate Professor of Neurology, Columbia University, New York, and H. Houston Merritt, M.D., Professor of Neurology, Columbia University. Cloth. $8. Pp. 401, with illustrations. F. A. Davis Company, 1914-16 Cherry St., Philadelphia 3, 1959.

This book is the product of 12 authors in various fields of medicine who have had wide experience in the diagnosis and treatment of patients with headache. Each author discusses the problem of headache from the standpoint of his specialty. There is some duplication in the text, for each author has been permitted to express his own viewpoint, but this seems to add to, rather than detract from, the volume. While the authors state in the preface that the book is written for the practicing physician, it is so comprehensive in its scope that physicians in all fields of medicine should find it interesting reading. Throughout the book, the basic mechanisms involved in the production of headache and head pain and the correction of these disturbances are stressed. The book has full chapters on mechanisms of headache; diagnostic principles and methods; principles of pharmacotherapy; the eyes, ears, nose, and throat as sources of headaches; migraine and tension headache; the role of allergy in headache; headache in systemic disease and in intracranial disorders; psychiatric and psychogenic factors in headache; the role of the cervical spine in headache and head pain; major cranial neuralgias; and the surgical treatment of headache. The chapter on principles of pharmacotherapy is especially good and should be of great interest to the general practitioner. Helpful therapeutic measures and prophylactic aids are adequately discussed. The approach to the headache problem is practical and, for the most part, thorough. Since temporal arteritis constitutes a medical emergency, more than the one and one-half pages allotted could have been devoted to the subject. Adequate references are given at the end of each chapter, and the book is well indexed.

The Upper Atmosphere. By H. S. W. Massey, Ph.D., D.Sc., F.R.S., and R. L. F. Boyd, Ph.D. Cloth. $17.50. Pp. 333, with illustrations. Philosophical Library, Inc., 15 E. 40th St., New York 16, 1959.

This book is doubly interesting because of the spectacular successes of the recent International Geophysical Year and the increasing importance of aviation in medicine. After an introductory chapter on the necessary fundamentals of physics, there are chapters on the methods used for studying the upper atmosphere (balloons, rockets, sound waves, radio waves), on the ozonosphere and ionosphere, on lights in the night sky (especially the aurora borealis), on regular and irregular magnetic phenomena in the atmosphere, on meteors and cosmic rays, and on artificial satellites. Commendable features are the wealth of new and instructive material in the first chapter, the concreteness of detail in the chapters that follow, the abundance and beauty of the illustrations, and the generally direct and unaffected style. An almost negligible fault is the use of obsolescent units and symbols in the table describing the first six artificial satellites. The bibliography is good and the index excellent. Readers prepared to follow the occasional mathematics will find the equations explicit and accurate. Readers not so prepared must learn to skip the mathematics and enjoy the rest; the experience should be rewarding.

Psychopharmacology: Problems in Evaluation. Proceedings of conference on evaluation of pharmacotherapy in mental illness sponsored by National Institute of Mental Health, National Academy of Sciences—National Research Council, and American Psychiatric Association, Washington, D. C., September 18-22, 1956. Edited by Jonathan O. Cole and Ralph W. Gerard. Publication 583, National Academy of Sciences—National Research Council. Conference supported by grant no. 3M-9104 from National Institute of Mental Health of National Institutes of Health, Public Health Service, Department of Health, Education, and Welfare. Cloth. $6.50. Pp. 662, with illustrations. National Academy of Sciences, National Research Council, 2101 Constitution Ave., Washington, D. C., 1959.

The six working papers which were prepared for the conference here reported reviewed, in a general way, the pharmacology of the drugs used in psychotherapy, effects on animal behavior, the reported results of clinical studies, their possible public health implications, and the more general problems of the evaluation of the effectiveness of any psychiatric therapy. The first section of the volume consists of these six working papers. Five committees were formed, composed mostly of members of the Committee on Preliminary Screening of Drugs, which thoroughly reviewed current knowledge of the basic mechanisms of action of these psychoactive compounds and, more particularly, the adequacy of available methods for the selection of the test animal and early human screening of compounds of this general sort. Three other committees were originally organized as a group, so that the field of clinical drug evaluation, which was the primary concern of

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

the conference, would receive the most thorough scrutiny possible. The general clinical area was divided into three sections. The first dealt with the problems attached to the selection of patient groups for study and the problem of adequate scientific controls in clinical researches. The second encompassed the influence of the environment in which the drug studies were done and the problems attached to drug administration itself. This area was expanded to include the more general aspects of test design in clinical drug evaluation. The third concerned itself with the problems of evaluation and the more detailed consideration of some of the available techniques for the measurement of change in psychiatric patients.

The committee on planning and coordination advised the National Institute of Mental Health about the formation of what is now called the Psychopharmacology Service Center. It had become increasingly apparent that there was serious need for a unit within the National Institute of Mental Health to concern itself specifically with the stimulation of research and the dissemination of information concerning the psychoactive drugs. This center was subsequently established with Dr. Jonathan Cole as its chief and Dr. Ralph Gerard as the chairman of its advisory committee. Because of the necessity for keeping this work from expanding into several volumes only that material which appeared to be most pertinent was included.

The summaries prepared by the various committees and presented to the main conference, together with discussion from the floor of these summaries, are included as a special section at the end of the volume and are followed by Dr. Seymour Kety's final analysis of the work of the conference and the consolidated recommendations of the various working groups. This volume contains the most valuable information on the evaluation of pharmacotherapy in mental illness that has ever been published. It is a storehouse of the current knowledge of this subject contributed by scientists who have engaged in research in this field. There is an author and discussant index, and a subject index.

A Textbook of Pharmacology and Therapeutics, Including Drugs and Solutions. By Harold N. Wright, M.S., Ph.D., Professor of Pharmacology, University of Minnesota, Minneapolis, and Mildred Montag, Ed.D., R.N., Professor of Nursing Education, Teachers College, Columbia University, New York. With appendix on Canadian drug legislation by Charles W. Nash, B.Sc., Ph.D., Professor of Pharmacology, Faculty of Medicine, University of Alberta, Edmonton, Canada. Seventh edition. Cloth. $5. Pp. 497, with 95 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

This new and extensively revised edition of an established textbook presents a wealth of up-to-date information about drugs and the newer, as well as the older, therapeutic agents in a concise and readable form. Students of nursing should find it an excellent introduction to pharmacology, and graduate nurses may find it useful as a brief reference work and a source of information about newer drugs.

The major portion of the text is devoted to a systematic review of the basic pharmacology, clinical uses, and toxicology of drugs currently employed in medical practice. A list of available preparations is given for each drug and conforms with the current editions of the U. S. P. and N. F., and the 1958 edition of New and Nonofficial Drugs. Doses are stated in both the metric and the apothecary systems, and both nonproprietary and trade names are included. A bibliography of relevant published papers is presented for each group of drugs.

There are also sections on phamaceutical preparations, techniques of administration of drugs, a review of arithmetic, a description of the elements and terminology of ward orders and prescriptions, a section on the emergency management of cases of poisoning, and a brief summary of drug legislation, both of the United States and of Canada. The material on the preparation and properties of solutions, a feature of earlier editions but more recently published separately, has been restored to the text.

The new format and typography are especially pleasing and contribute significantly to the clarity of the presentation. This is one of the better available pharmacology textbooks written specifically for nurses. Since the book is not directed to physicians and medical students, no criticism is implied in pointing out that these groups would probably find the book insufficiently detailed for their purposes.

Medical Department, United States Army, Surgeon in World War II. Volume II: General Surgery. Prepared under direction of Major General S. B. Hays, Surgeon General, United States Army. Editor in chief: Colonel John Boyd Coates, Jr. Editor for general surgery: Michael E. DeBakey, M.D. Associate editors: W. Philip Giddings, M.D., and Elizabeth M. McFetridge, M.A. Office of Surgeon General, Department of Army, Washington, D. C. Cloth. $4.25. Pp. 417, with 43 illustrations. Superintendent of Documents, Govern. Print. Off., Washington 25, D. C., 1955.

This volume comprises a clear and succinct account of the methods so successfully used by American Army surgeons in World War II. These methods represented a distinct advance over those used in World War I and resulted in a much lower death rate than had ever before been experienced among the wounded of any war.

One reason for the improvement was shortening the elapsed time between injury and operation. Previously the patients had been handled too much and transported too far and there were too many delays for inspection along the line of evacuation.

This was corrected by operating on all acute emergencies in the forward areas. Resuscitation was vastly improved, and it was learned early that plasma was not an adequate substitute for whole blood. The use of oxygen was highly important. Cyanosis could be easily overlooked in a hasty examination under a poor light in the preoperative tent. The importance of emptying the stomach preoperatively was recognized early. Abdominal surgery, which was largely neglected in World War I, made a great advance in World War II, principally due to early operation and to the invariable rule that all wounds of the large intestine should be exteriorized or, if that is not possible, must have a colostomy proximal to the wound. It was learned that methods involving suture and packing of liver wounds did not give good results but were followed by secondary hemorrhage, abscess formation, or liver necrosis. Most liver wounds stop bleeding spontaneously. Exploration and drainage of Morison's pouch to prevent biliary peritonitis was the method eventually evolved.

The transdiaphragmatic approach to thoracoabdominal wounds was another advance. It was also learned that too much morphine had been given previously. Repeated doses when a soldier was wet, chilled, and his circulation poor resulted in nonabsorption and subsequent poisoning when he was warmed up and resuscitated in the preoperative tent. This book makes a valuable contribution to the subject of traumatic surgery.

The Comparative Anatomy and Physiology of the Nose and Paranasal Sinuses. By Sir Victor Negus, D.Sc., M.S., F.R.C.S. Cloth. $14. Pp. 402, with 178 illustrations. [Williams & Wilkins Company, 428 E. Preston St., Baltimore 2]; E & S Livingstone, Ltd., 16 & 17 Teviot Pl., Edinburgh 1, Scotland, 1958.

In 1929 a monograph on the comparative anatomy and physiology of the larynx appeared. The anatomic and physiological investigations on which this monograph was based took seven or eight years and were made at various institutions, among them the Zoological Society, the Museum of the Royal College of Surgeons in London, and the laboratories of Kings College. This study on the mechanism of the larynx throughout the animal kingdom, its interrelation with olfaction, respiration, phonation, and possibly other functions, was painstakingly undertaken. All this, presumably in his spare time, was done by one whose chief interest was that of a practitioner and "student" of the ear, nose, and throat in health and disease. This monograph on the larynx at once became a classic and has so remained.

The collection in the Museum of the Royal College of Surgeons of England which illustrates the anatomy of the human nose and sinuses, and which was arranged about the famous aggregation of specimens of Professor Onodi of Budapest, was almost completely destroyed during the bombing of London in 1941. The author, prompted by the need for reconstruction of this collection and using the ample materials of the storerooms of the College of Surgeons, once more devoted the leisure time of several years to this task and, in addition, supplemented the human material with specimens from various animals, including fish, amphibia, reptiles, birds, and mammals.

The result of these labors is comparable to that first work on the larynx. This handsomely bound and printed volume, embellished with numerous illustrations, nearly all of them original, describes the comparative anatomy and physiology of the nose. The discussion is concerned with olfactory, respiratory, and air-conditioning mechanisms of the nose, and other functions; attention is also paid to the comparative anatomy and physiology of the paranasal sinuses. The work ends with a section on the human aspects of the nose and its accessory air chambers. It contains a wealth of authoritative information and should be welcomed by all those who have an interest in the area it covers in so scholarly a fashion.

Perspectives in Virology: A Symposium. Edited by Morris Pollard. [Third in series of scientific symposia and proceedings sponsored by Hartz Mountain Products Corporation, New York.] Cloth. $7. Pp. 312, with illustrations. Published for Institute of Microbiology, Rutgers University, by John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W. C. 2, England, 1959.

This book is a memorial to F. R. Beandette, a distinguished agricultural scientist. Twenty distinguished investigators present papers on different aspects of virology. These are in the nature of reviews but often include new work of the authors. Papers on basic aspects of viruses include the chemical nature of the tobacco mosaic virus, viral multiplication and transformation, nutritional requirements of viruses and cells, and cell-plating techniques. The present status of the measles virus and of 70 new human viruses, the epidemiology of influenza, and the natural history of hog cholera are brilliantly presented. Four papers on viral neoplasia outline this exciting new area. The presentations on influenza, on measles, and on the new viruses should be of special interest to the clinician. The others, while excellently done, are too technical to appeal to any but the virologists. The foreword contains a tribute to Beandette, and the epilogue a delightful piece entitled Tulipomania and the Benevolent Virus. The discussions of the papers are lively and stimulating, and there is a comprehensive bibliography for each. This is an excellent book for the graduate student and specialist in virology.

QUESTIONS AND ANSWERS

TREATMENT AND PROPHYLAXIS OF TETANUS

To the Editor:—*What dose of tetanus antitoxin should be used in treatment of a patient who has active tetanus, has not received any immunization or prophylaxis, and who had no history of injury prior to development of clinical symptoms of tetanus? Also, within what period after a tetanus booster has been given is it safe to omit another booster if a minor injury occurs such as a nail puncture or small laceration?*

John H. Cordes Jr., M.D., St. Petersburg, Fla.

Answer.—A minimum of 160,000 units and a maximum of 320,000 units of tetanus antitoxin may be used in therapy of acute tetanus. After débridement with the patient under sedation, 60,000 units is given around and proximal to the wound, if identified. The balance is given into the gluteal muscles. The dosage depends on age, sex, weight, and shortness of incubation period; the shorter the period the higher the dose. Only one sensitivity test before giving the tetanus antitoxin has proved safe: Dilute 0.1 cc. of tetanus antitoxin in 10 cc. of isotonic sodium chloride solution. Take the patient's blood pressure. Slowly inject the solution into a vein. The systolic blood pressure should not drop lower than 20 mm. Hg in a child or 30 in an adult or desensitization must be used before giving the antitoxin. The last 40,000 units of the dose selected may be given intravenously in isotonic sodium chloride, not dextrose, solution. A toxoid booster is always indicated after the type of accident mentioned. There is no contraindication.

EMERGENCY USE OF TETANUS IMMUNIZATION

To the Editor:—*In our two local hospitals we are about to adopt the following precautions against tetanus:*

1. No previous tetanus toxoid: 1,500 units of tetanus antitoxin after skin test, with larger dosage in massive wounds. It is also recommended that the patient be given 0.5 cc. of tetanus toxoid in another extremity with a second similar dose four weeks later. (This offers no protection for the current injury, but the two injections then give basic tetanus protection.)

2. Last booster dose of tetanus toxoid more than five years prior to injury: Same as above with omission of second toxoid injection, since the first injection will act as a booster to restore a protective serum antitoxin level.

3. Last booster dose of tetanus toxoid less than five years prior to injury: 0.5 cc. of tetanus toxoid.

4. Last booster dose of tetanus toxoid less than one year prior to injury: No booster required. Give booster if there is any question as to accuracy of dates.

Are there any further suggestions?

William S. Dempsey, M.D., St. Albans, Vt.

Answer.—The suggested hospital precautions against tetanus for lacerations, abrasions, burns, and puncture wounds are in accord with standard procedure. To be more conservative, the first paragraph should be changed to read 3,000 units of tetanus antitoxin instead of 1,500. The second paragraph could be modified in that for minor wounds and abrasions a prior injection of toxoid would be considered effective for 10 years. For severe or heavily contaminated injuries, however, particularly compound skull fractures, 5,000 units of tetanus antitoxin plus an additional 0.5 cc. of tetanus toxoid should be used. Paragraph 4 could be omitted altogether. Irrespective of the interval after the last tetanus toxoid booster, an additional booster should be given at the time of injury. Paragraph 3 would cover all situations not covered in 1 or 2 where toxoid had been given less than 10 years prior to injury.

MASS TETANUS IMMUNIZATION

To the Editor:—*The Morris County (N. J.) Medical Society has decided to promote mass inoculation of as many of its citizens as possible with tetanus toxoid, as was done for servicemen. Has an endeavor of this kind been carried out before? Is there any information on promotional propaganda techniques and how best to accomplish the purpose?*

Sam C. Atkinson, M.D., Summit, N. J.

Answer.—In various forms, programs for large-scale immunization of civilian adult groups against tetanus have been carried out by both formal and informal methods. The formal approaches utilize newspapers, including local weekly neighborhood publications; radio, with announcements sponsored by the local medical society; television, sponsored by the local medical society and through popular

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

news commentators; placards in buses and other public conveyances and in places where adults tend to gather in moderate to large numbers; house-to-house canvass by Boy Scouts and Girl Scouts, who distribute printed material; clinics arranged for convenience of working people, with prearranged fee schedules at a nominal level; and Parent-Teacher Association addresses.

The informal method involves the use of printed and verbal propaganda in physician's offices and hospitals. Pediatricians are strategically placed to encourage immunization of adults. The local pediatric society should be consulted in this program. Likewise, organized industry can be enlisted.

Printed material of various types is available from state health agencies, various health agencies, from various biological houses, and the several agencies associated with the National Institutes of Health, Bethesda, Md.

TOXIC NEURITIS PRODUCED BY TETANUS TOXOID

To the Editor:—*Have there been cases of toxic neuritis after inoculation for tetanus? If so, what is the proper treatment?* M.D., *Illinois.*

Answer.—This consultant has seen two cases of toxic neuritis after inoculation for tetanus. In both, the involvement was of the shoulder girdle muscles and consisted chiefly of severe motor weakness of the shoulder abductors. No specific treatment is available. Both patients were treated with vitamin B_{12} in doses of 1,000 mcg. daily. In one case the condition cleared promptly, while in the second there was 50% residual damage in spite of intensive physical therapy.

Answer.—The question does not specify the prophylactic agent employed, i. e., antitoxin or toxoid. The literature relates more to antitoxin, thus this response will be governed accordingly. The presence of extraneous materials in tetanus toxoid has allergenic potential and would be a possible factor in eliciting so-called toxic neuritis on an allergic basis.

Neuritis secondary to the administration of tetanus antitoxin includes optic neuritis (with blurring of the optic disks and gradual return to normal), involvement of the auditory nerve (marked deafness during the course of serum sickness and subsequent recovery of almost normal hearing), paralysis of the recurrent laryngeal nerve (with recovery in two to five months after onset), and peripheral neuritis of the spinal nerves, mainly those supplying the upper extremities (upper or whole brachial plexus) but not omitting those nerves derived from the lumbar plexus. The involvement may be unilateral or bilateral, and pure radial involvement may occur.

Tetanus toxoid may contain allergens. The not infrequent occurrence of serum sickness of the delayed type after tetanus toxoid administration would validate anticipation of allergic neuritis in some instances. Treatment would consist of antihistamines, steroids, corticotropin, physiotherapy, and precaution with subsequent use of the agent. Reference may be made to an article by Spaeth (*Nebraska M. J.* 41:224 [June] 1956).

TOXOID ALLERGIC REACTION

To the Editor:—*Please give information regarding allergic reaction in a patient taking tetanus toxoid immunization. The patient is a 54-year-old woman. Several years ago she apparently had a tetanus antitoxin skin test and injection to which she had an allergic reaction. She said she was told then that she would also be allergic to tetanus toxoid; however, it was recommended that she take the toxoid series and she was given 0.5 cc. of alum-precipitated tetanus toxoid. Several hours later, the patient telephoned and said she was beginning to break out with hives. She was given chlorpheniramine maleate, 12 mg. twice a day, which controlled the hives quite well. This reaction lasted with mild to moderate severity for about one week. The patient has no history of allergy other than this episode and has been in general good health. What would be the recommended procedure in immunizing this patient for tetanus?*

John A. Lauer, M.D., Clearwater, Fla.

Answer.—The circumstances would suggest that the earlier allergic reaction to tetanus toxoid was secondary to previous sensitization to some component of the preparation. In searching for this component, it would be advisable to communicate with the manufacturer to determine the materials and procedures employed in the sequences of preparation. With this information, appropriate tests for allergic hypersensitivity could provide tentative information concerning cause of the reaction. If one or multiple components should be incriminated, correspondence with other biological houses could be instituted to locate a vaccine (toxoid) not containing the noxious component(s). If such material is not available, repeated minute doses of diluted vaccine (1:1,000 to 1:100) could be administered until the tetanus antitoxin titer reaches a protective level of 0.1 unit per cubic centimeter or higher. After an initial dose of 0.5 cc. of toxoid, it is likely that several minute doses of toxoid would produce an adequate protective titer. Although the present circumstance augurs well immunologically for a minute additional dose of tetanus toxoid (because of a relatively large initial dose of 0.5 cc.), less favorable circumstances would permit the induction of active immunity on the basis of repeated minute doses of toxoid, guided by titrations of the subject's blood serum after five or more doses of 0.1 cc. of 1:1,000 to 1:100 dilutions of tetanus toxoid. Such a procedure utilizes the principle of "immunological momentum" (Spaeth, *Nebraska M. J.* 42:112, 1957). To protect against acute anaphylactic shock, dosage with a 1:1,000 solution of epinephrine hydrochloride should be provided with each injection and antihistaminic drugs should be prescribed. Arrangements should be made with the biological house for titration studies.

REACTIONS AFTER INJECTION OF TETANUS TOXOID

To the Editor:—*In the reply to the question entitled "Reactions After Injection of Tetanus Toxoid" in* The Journal, *March 21, 1959, page 1398, there is a recommendation which could be misleading. The correspondent and consultant agree that the symptoms described are of the serum sickness type, however, the consultant makes the following statement and recommendation:*

"Sensitivity tests could be conducted with the various anticedent materials" and "avoidance of reactions at later dates could be effected by . . . use of another company's toxoid preceded by allergy tests to exclude sensitivity to the newly selected material." The reader would be led to believe that a diagnostic skin test can forecast the occurrence of a delayed serum sickness type of reaction. This is erroneous. A positive result denotes the possibility of the patient having an immediate or anaphylactic type of reaction. The serum sickness reaction is never preceded by a positive result because the illness is produced only after the antibody which is developed in the days after the injection reacts with the residue of antigen. Once the serum sickness has been produced, the test result may become positive; even then, results of the sensitivity test are of a low degree and tend to last for a short time.

S. M. Feinberg, M.D.
Northwestern University
303 E. Chicago Ave.
Chicago 11.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*Since there is no disagreement concerning the status of acquired hypersensitivity in the patients mentioned by the original correspondent, the use of the skin test to detect the persistence of this acquired sensitivity is in accord with accepted principles of immunology (Spaeth:* Nebraska M. J. *42:112 [March] 1957). If the skin test is used to predict the acquisition of specific hypersensitivity on a* de novo *basis, an error in the understanding of the underlying mechanism must be corrected which leads many physicians to make the statement that the patient developed delayed serum sickness despite a negative skin test. It should be emphatically stated that the skin test (as well as the ophthalmic test) detects present, rather than future, specific hypersensitivity.*

ENLARGED COSTOCHONDRAL JOINTS

To the Editor:—*I wish to interject another consideration to the question in* The Journal, *March 21, page 1399, on painful enlargement of costochondral joints. The patient in question was not relieved by the local injection of prednisone, and orally given prednisone, apparently, was not administered. Systemic steroid therapy has been successful in the management of pain in some of these cases (McSweeney and others:* A. M. A. Arch. Int. Med. **102**:459, *1958). This conservative approach could be given a trial before one proceeds with resection of the affected rib cartilage. Since the ailment is benign and self-limited, swift removal of the offending tissue seems inappropriate. The pain of costal chondritis (Tietze's disease) generally reaches a maximum within a day or two and then gradually subsides over a period of three weeks or more. It is possible that the discomfort which attends operative therapy might last beyond the natural course of the malady.*

Austin J. McSweeney, M.D.,
500 W. Milwaukee St., Jonesville, Wis.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*The physician who sent the question about enlarged costochondral joints did not state how long these joints had been enlarged. The fact that various treatments had been undertaken and pain persisted, so that it was difficult for the patient to do his work, led to the opinion that this was a chronic condition and not a self-limited condition such as costal chondritis. Some of these conditions are the result of trauma, and those which this consultant has treated by operative management have caused the patient difficulty for months or years before being definitely treated. If the condition described by the physician asking the question had been present for only two or three weeks or could be diagnosed as costal chondritis, then certainly the management should be conservative and systemic steroid therapy should be of marked benefit to the patient.*

Hearings on Aged . .

FINAL KEOGH-SIMPSON BILL HEARING

The Senate Finance Committee heard spokesmen from 10 organizations urge approval of the Keogh-Simpson bill at the Committee's final hearing on the legislation this year. Despite the favorable testimony during the final, one-day session and at earlier hearings from scores of organizations representing the self-employed, it was not certain that the Committee would vote on the bill this session.

Speaking for the American Dental Association, Dr. Floyd W. Pillars declared that under the present tax set-up dentists have "little opportunity . . . to establish a suitable retirement program. Typically, the dentist is seldom encouraged at any stage of his career to allocate funds regularly for his later years."

The Keogh-Simpson bill, overwhelmingly approved by the House this year, provides tax deferrals for self-employed persons on money set aside in qualified pension or retirement plans. It is intended to give the self-employed, such as lawyers, farmers, dentists, and physicians, similar tax treatment to that now afforded salaried persons covered by company pension plans.

Dr. Pillars, an oral surgeon from Des Moines, Iowa, said the Committee, headed by Sen. Harry F. Byrd (D., Va.), "might well reflect on the growing difficulty that is foreseen in attracting young, capable people to the self-employed professions" due to the "economic uncertainty involved."

Most salaried persons, he noted, "not only may be assured of a definite income while they are working, but usually the company by which they are employed has a plan for income after retirement."

"There would appear to be no sound reason for encouraging the establishment of pension plans for the employes of business organizations without providing the same encouragement for the establishment of plans for those who employ themselves," he testified. With the number of aged citizens increasing, "it would seem prudent and logical to act now to encourage additional people to provide for themselves the security they will need after they have reached retirement age and have lost all or part of their earning power."

Other organizations that recommended passage of the bill at the final hearing included the Investment Counsel Association of America, Inc., American Institute of Architects, American Society of Industrial Designers, Junior Bar Conference of American Bar Association, Authors League of America, Mobilehome Dealers National Association, National Association of Plumbing Contractors, and National Live Stock Committee.

Meanwhile, Sen. Gordon Allott (R., Colo.) joined Sen. Thruston B. Morton (R., Ky.), Republican national chairman, in sponsoring the Keogh-Simpson bill from the Republican side of the Senate aisle. In a Senate speech Allott said the impact on federal revenues is the only major objection to the legislation, and that the Treasury Department's price tag of 365 million dollars "seems entirely unlikely."

This estimate assumes that the self-employed will invest 1 billion dollars in retirement plans the first year, he said, adding that "there is little reason to assume that a million self-employed will immediately deposit $1,000 each under this plan. Indeed, surveys indicate that only about 50% of the self-employed intend to utilize the plan at all."

Allott said the immediate revenue loss would probably be 75 to 100 million dollars, as estimated by the Tax Foundation and Prof. Roger Murray of Columbia University. However, he pointed out that the invested funds would "add to the capital financing available for the further economic growth we all favor. . . . By thus helping to build American enterprise, we in turn would provide additional sources of tax revenue to help offset any loss," the senator said. "To hold off passage of the measure longer," he told the Senate, "is to compound inequity."

A. M. A. BACKS BROAD WARNING LABEL BILL

The American Medical Association asked Congress to approve a "broad law which requires the precautionary labeling of hazardous substances at the national level."

In a letter to the Senate Commerce Committee Dr. F. J. L. Blasingame, A. M. A. executive Vice-president, declared that since the present federal labeling law was enacted in 1927, "many new compounds for household, commercial, and industrial use have been introduced which are not covered by the . . . legislation."

The measure before the committee, headed by Sen. Warren G. Magnuson (D., Wash.), would replace existing statutes and provide more comprehensive coverage of products requiring labeling, as well as more detailed labeling standards. Flammable as well as potentially poisonous products would be covered.

(Continued on next page)

tial dose of 0.5 cc.), less favorable circumstances would permit the induction of active immunity on the basis of repeated minute doses of toxoid, guided by titrations of the subject's blood serum after five or more doses of 0.1 cc. of 1:1,000 to 1:100 dilutions of tetanus toxoid. BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

"Lack of information about hazardous ingredients in cases of poisonings have enhanced their gravity by complicating or delaying treatment," said Dr. Blasingame. "The law should require informative labeling, which would include a list of hazardous ingredients, their potentialities for harm, directions for safe use, and first-aid instructions."

Dr. Blasingame called for clear, outstanding warning symbols to facilitate recognition, declaring that in practice few persons are sufficiently impressed by such words as "danger," "warning," or "caution." Consideration should be given, he said, to the use of such familiar warning symbols as a flame for inflammable substances and a skull and crossbones for poisonous substances. Different pictorial symbols should be used according to the danger of the products, he said.

The measure before the Committee should be broadened to apply to all hazardous substances "distributed as packaged chemicals for nonmanufacturing purposes," rather than simply to those "intended or suitable for household use," said Dr. Blasingame.

He noted that the A. M. A.'s Committee on Toxicology had spent two years studying the problem and made recommendations concerning the need for more sweeping labeling requirements.

INCIDENCE OF POLIOMYELITIS RISES

Although the rate of climb has diminished, the number of paralytic poliomyelitis cases continued to rise through the week ending Aug. 1, with 183 cases reported to the U. S. Public Health Service. This was a weekly high for the year.

The 183 cases compared with 175 cases the week before and 166 the previous week when there was a 50% jump in cases.

Through the month of July 1,134 paralytic polio cases were reported, in contrast to 579 during the same period last year and 2,525 in 1955 before Salk vaccine was in widespread use.

The latest cases represented small clusters in most parts of the country, said PHS, with the exception of New Haven, Conn., which was classified as the only epidemic area.

From the first of the year through Aug. 1, drug manufacturers produced 50,764,371 doses of vaccine, compared with 47,141,871 doses during the same period last year.

NURSING HOME AID AGAIN VOTED

The program to encourage construction of proprietary nursing homes survived maneuvers in a political tug of war between Congress and President Eisenhower on housing legislation.

After the Senate failed to override the chief executive's veto of a previous housing bill, the Senate Banking Committee approved a $1,050,000,000 program, scaled down from the 1.4-billion-dollar bill that was vetoed.

The bill was identical to one cleared by a Senate banking subcommittee, except for a change in the method of financing a college classroom program.

The new measure provided Federal Housing Administration loan guarantees for construction of proprietary nursing homes.

The noncontroversial loan guarantee program, backed by the American Medical Association, was part of the vetoed bill as well as the compromise measure. The full Banking Committee had first decided by an 8 to 7 vote to attempt to override the veto and, when this was unsuccessful, voted the compromise.

Other sections of the housing measure of interest to physicians would provide $62,500,000 for interns' and nurses' housing under the college housing program, and establish a 50-million-dollar revolving fund for direct loans to help private nonprofit corporations build rental housing for the elderly. The Banking Committee trimmed the $62,500,000 for interns' housing to 25 million dollars, but did not change the provision on housing for the elderly which President Eisenhower had criticized in his veto message.

SCHEDULE FOR HEARINGS ON AGED TENTATIVELY SET

The special Senate labor subcommittee investigating problems of the aged planned more than a month of hearing in cities across the country after Congress adjourns.

Sen. Pat McNamara (D., Mich.), Chairman of the group, said he would call witnesses to testify on all aspects of aging, including medical care, finances, and employment policies.

Cities under consideration for subcommittee visits included Detroit, Grand Rapids, and Lansing, Mich.; San Francisco; Miami, Fla.; Boston; and cities in Pennsylvania and West Virginia. The sessions will begin the second week in October and continue into the month of December.

MISCELLANY

U. S. Surgeon General Leroy E. Burney appointed an ad hoc committee of 10 state health officials and 2 representatives of the Public Health Service "to develop a basis for improved planning of mental health facilities throughout the nation." Dr. Burney said the committee was formed in response to a recommendation of state health authorities.

Major Gen. Leonard D. Heaton, surgeon general of the Army, was nominated by President Eisenhower for promotion to Lieutenant General. The 56-year-old officer's nomination is subject to confirmation by the Senate.

Public Health Service awarded $11,200,000 in grants to help build and equip additional health research facilities in 47 institutions. The grants are designed to improve and expand the nation's facilities for medical and dental schools, schools of public health, and other research institutions. Largest grants were $1,297,955 to the University of Oregon medical school, and $1,292,975 for the University of California.

A new, agency-wide committee was established by the Veterans Administration to make a sweeping study of medical, social, and economic problems of aging veterans. VA Deputy Administrator Bradford Morse will head the committee. The VA pointed out that, in 12 years, 16 million of 22 million veterans of World War II will be over 45 years of age.

INTRAFAMILIAL AND INTERFAMILIAL SPREAD OF LIVING VACCINE STRAINS OF POLIOVIRUSES

Henry M. Gelfand, M.D., Louis Potash, Ph.D., Dorothy R. LeBlanc, R.N.
and
John P. Fox, M.D., Ph.D., New Orleans

Fifty-six household units participated in a study of the spread of poliovirus within families and between families. Within this group all persons above the age of 6 months and not naturally immune had previously received the Salk vaccine. Each of the families used included at least three naturally susceptible members. Sabin vaccine was administered by squirting 1 ml. of the single-strain virus suspension into the back of the recipient's mouth. All but one adult was successfully infected after receiving the recommended dose. Virologic and serologic methods demonstrated transmission to many contacts, fecal excretion of the virus being the most sensitive indicator of that fact. The virus commonly appeared in the pharyngeal secretion within the first two days. The most important factor favoring intrafamilial transmission was low socioeconomic status. No evidence was found to suggest that any illness, however minor, followed the administration or spread of any of the three vaccine virus strains used.

With the isolation, selection, purification, and large-scale production by Koprowski,[1] Sabin,[2] and Roca-Garcia and others[3] of attenuated variants of polioviruses of all three types, we are offered the opportunity to substitute live-virus vaccination against poliomyelitis for the formalin-inactivated vaccine in current use.

Among the generally accepted advantages of vaccination with the infectious strains we may list (1) the ease of administration: oral versus parenteral administration; (2) the duration of protection: theoretically life-long; (3) the percentage of effectiveness: perhaps close to 100% versus the 70 to 80% now attained by Salk vaccine; (4) the rapidity of effective immunization: making possible its use in established epidemics; and (5) the "herd" immunity produced: by inducing local intestinal resistance. The generally recognized disadvantages include (1) the necessity for an interval of some weeks between the administration of the different types and (2) the danger of accidental contamination of the vaccine by other living microbial material. The latter danger can be obviated by proper care during production and safety testing afterward, and the former may be overcome by future technical development.

A controversial characteristic of live-virus poliomyelitis vaccination is the ability of these strains to be transmitted from the vaccinated person to his

---

contacts. The very earliest work with living attenuated polioviruses showed that, some days after oral administration, they are excreted in the feces. Subsequently, Koprowski and others,[4] Dick and others,[5] Horstmann,[6] Martins da Silva and others,[7] Smorodintsev,[8] Sabin,[9] and Gard,[10] using various strains of all three types, have unequivocally demonstrated spread to susceptible persons under various conditions of contact. In itself, the occurrence of this phenomenon probably would be of little concern, were it not for the possibility that the fecally excreted viruses being spread may have undergone back-mutation to a level of neurovirulence greater than was acceptable in the original oral vaccine. One might well take the even more extreme position that, were it not for this possibility of back-mutation, spread of vaccine viruses by contagion is a decided advantage of live-virus vaccination, in that the administration of vaccine to only a portion of the population might result in the effective vaccination of the entire population. This would be vaccine-induced "herd protection" of a level not yet achieved with any immunizing agent.

The demonstrated tendency of attenuated strains of poliovirus to change in the direction of increased virulence on multiplication in the intestinal tract may have little practical significance in human beings, but a final conclusion is as yet unwarranted. Intraneural tests of the excreted viruses have yielded inconsistent results in the hands of different investigators and, moreover, no one has ventured to suggest what the maximum tolerable reversion might be. Regardless of the eventual result of this disagreement, knowledge of the infectivity and transmissibility of the vaccine strains is essential to their rational use in field trials and, eventually, in routine practice. The present communication will report, in preliminary fashion, the results of studies on the capacity of a set of vaccine strains to spread within families living under normal conditions in southern Louisiana.

Material and Methods

Population Studied.—Families for the present investigation were recruited in 1958 from a group in New Orleans which had been under our observation from 1953 through 1957 in a study of natural infection with polioviruses.[11] Their infection history was therefore unusually well known. During 1956 and 1957 all persons above the age of 6 months and not naturally immune to all three poliovirus types had been given three suitably spaced inoculations with Salk vaccine. Infants who were under 6 months of age at the beginning of this study were not vaccinated after it began.

To be eligible for the present purpose, a family had to include, for any given type, at least three "naturally susceptible" members, defined as persons without prior natural homologous infection as observed by us and coupled with the complete absence of naturally acquired serum-neutralizing antibody as measured by the direct cytopathic test. On this basis, a family might be "eligible" for more than one type, and many were used two or three times. Each feeding and family observation was therefore designated as a separate "unit" and so reported below. In addition, in several instances the same virus type was fed more than once in a single household when the first failed to cause infection and/or spread. Again, each feeding was considered a separate unit of study. On a few occasions, the vaccine was purposefully fed to naturally immune persons in households which also contained two homologously susceptible persons as indicators of spread. These units are separately considered. Family units were assigned to one of three socioeconomic categories: Caucasian–upper economic, Caucasian–lower economic, and Negro. The Caucasian group was divided on the basis of an aggregate family income of $3,500 per year (in 1953), and all Negro families fell below this level. Although arbitrary, this economic division was rather well correlated with social and sanitary facilities and practices such as household crowding, adequacy of toilet and hand-washing equipment, and "personal hygiene." Since there has been no prior evidence that race as such plays any part in the transmission of polioviruses, units usually are combined below only as upper economic or lower economic.

Virus Strains and Vaccine Administration.—The viruses used were kindly provided by Dr. Albert Sabin and were from single large pools of each type that had fulfilled his rigid criteria for purity and attenuation.[2] These strains were designated L Sc, 2 ab (type 1), P 712, Ch 2 ab (type 2), and Leon 12 a_1b (type 3). The stock material, undiluted or diluted as necessary with Hank's balanced salt solution, was distributed in 1.2-ml. aliquots into individual screw-topped vials, which were then kept at −20 C until used. The doses fed were calculated to contain approximately 100,000 (5 log doses) or 10,000,000 (7 log doses) infectious particles. Repeated titration of sample vials in cultures of rhesus kidney cells showed that actually an average of 5.3 and 7.3 log doses (type 1) and 5.1 and 7.1 log doses (types 2 and 3) had been used although, by error, a few persons received 3.6 log doses (4,000 infectious units) early in the study. These figures may need some upward revision for, in a recent communication, Sabin [9] reports that higher titers of his vaccine pools may be obtained by titration in cynomologous kidney-cell tissue cultures and an improved technique. Consequently, the doses we used may have been greater than reported here, i. e., approximately 4.3, 6.0, and 8.0 log doses (type 1), 5.3 and 7.3 log doses (type 2), and 3.9, 5.4, and 7.4 log doses (type 3).

Administration of the Sabin vaccine was done in the recipients' homes by one of us (D. R. L.) by squirting 1 ml. of the single-strain virus suspension into the back of their mouths, after which they drank a glass of water. The vials of vaccine were carried into the field on ice, and were never used for more than six hours from the time of leaving the laboratory. Several titrations of vials returned to the laboratory after that time showed that no significant titer decline had occurred. Individual medicine droppers were used in administration, and extreme care was taken to prevent contamination of the skin of the recipient or of objects in the home.

Method of Study and Collection of Specimens.—For each family unit of study, one susceptible person was chosen for administration of the homologous type of vaccine virus and was designated the "index" person. The two or more other susceptible persons and the naturally immune household members were all observed as "family contacts." In a few instances, observations were made on the possible spread of these viruses to other persons not living in the same domicile who are referred to as "extra-household" contacts.

TABLE 1.—*Schedules of Specimen Collection*

Donors	Type of Specimen	Days After Vaccine Feeding on Which Indicated Specimens Were Collected		
		Complete Schedule	Modified Schedule	Abbreviated Schedule
Index person	Blood	0, 3, 7, 11, 14, 18, 21, 60	0, 8, 20, 60	0, 60
	Pharyngeal	0-11	0, 2, 4, 8	None
	Fecal	0-14, 18, 21, 25, 28; 1 x per wk. to termination	0, 2, 4, 8; 1 x per wk. to termination	0; 1-2 x per wk. for variable period
Family contacts	Blood	0, 60	0, 20, 60	Same as index
	Pharyngeal	3-17	0	
	Fecal	0, 3-17, 21, 25, 28, 31; 1 x per wk. to termination	Same as index	
Extra-household contacts	Blood	0, 60	None	None
	Fecal	7, 14, 21		
No. of household units completed by indicated schedule		26	17	8 (plus 5 immune feedings)

The various schedules of specimen collection are outlined in table 1. Day "0" is the day of feeding in all instances. These schedules were set up as guides only and were often modified to suit the individual situations found in many households.

Blood specimens were almost always collected by venipuncture, with use of vacuum bleeding tubes; less than 1% were by heel puncture in small infants. Pharyngeal specimens were obtained from adults and older children by gargling. Screw-topped ointment jars were prepared with 7 ml. of tissue-culture maintenance fluid; this provided the gargle fluid, and it was expectorated back into the same container. With small children, the tonsillar area and posterior pharynx were thoroughly swabbed with a dry cotton-tipped applicator, and the latter was then dropped into a tube containing 5 ml. of maintenance fluid. Fecal specimens consisted of a pellet of whole feces placed into an ointment jar. Specimens were held at refrigerator temperature, usually no longer than overnight, before processing in the laboratory.

During the investigation of a number of family units, an attempt was made to detect the presence of poliovirus on the skin of the hands and buttocks of some children, and on the floor, on toys, and on other fomites. For this purpose, cotton pledgets wetted with Hank's solution were swabbed over the appropriate surface and returned to the laboratory, where they were squeezed almost dry. The resulting fluid was treated as indicated below for fecal extracts and pharyngeal gargles.

Laboratory Procedures.—Rhesus monkey kidney-cell tissue cultures, prepared in this laboratory, were employed throughout, with use of techniques now standard.[11]

For virus isolation, stool specimens were processed into 10 to 20% fecal extracts containing penicillin, streptomycin, and nystatin (Mycostatin), while pharyngeal specimens were used as collected, after centrifugation and the addition of antibiotics. Each of four tissue-culture tubes was inoculated with 0.25 ml. of each specimen. The latter were incubated at 37 C and examined at intervals for 10 to 13 days, with a change of lactalbumin maintenance medium fluid on the fourth to seventh day. Specimens were recorded as negative if there was no evidence of a cytopathic effect after this time; if doubtful, the supernatants were pooled, and a subculture was made by inoculating 0.1 ml. of the pooled material into each of two new tubes which were then incubated for four to seven days. When a cytopathogenic agent was recovered, identification was first attempted by neutralization with hyperimmune rabbit antiserum prepared against the virus of the type fed. If complete neutralization did not occur, further investigation was made with the use of polyvalent serums against the other types of polioviruses, Coxsackie viruses A9 and B1-5, and ECHO types 1 to 14, followed by the appropriate monotypic tests.

Serums were tested for the presence of neutralizing antibody in the direct cytopathic test for the high-avidity antibody of Sabin.[9] Aliquots of each serum dilution were incubated for one hour at room temperature, with an equal quantity of virus suspension calculated to contain approximately 100 tissue culture infective doses ($TCID_{50}$) per 0.1 ml. For index persons, four tubes were used per twofold dilution and for contact persons, two tubes per twofold dilution. End-points are expressed as of the final serum dilution.

Results

The available data relating to 56 family units are the subject of this preliminary report. In 51 units, a naturally susceptible person was fed, the distribution of these by socioeconomic and family status being as follows: Negro, 13 children only; Caucasion-lower economic, 13 children only; and Caucasian-upper economic, 18 children and 7 parents. In five additional units, a homologously naturally immune index person was fed.

Infections in Susceptible "Index" Persons.—Of the 51 feedings represented by these household units, all but five resulted in the infection of the index person, as indicated by the subsequent recovery of homologous virus from the pharyngeal and/or fecal excretions. As may be seen in detail in table 2, four of these failures were in persons who had received the small 3.6 log dose of type 1 vaccine. One of the four failures was an adult, who was then refed with 5.3 log doses of the same virus type. Again he failed to become infected, representing the fifth and last feeding failure. He was refed once more, with 7.3 log doses of the same type, and thereupon excreted virus fecally for five days.

Table 2.—*Summary of Efforts to Recover Virus from Pharynges and Feces of Index Persons Fed "Sabin Vaccine," by Virus Type, Dose, and Family Status*

			Homologous Virus Detected in Appropriately Collected Specimens			
			Pharyngeal		Fecal

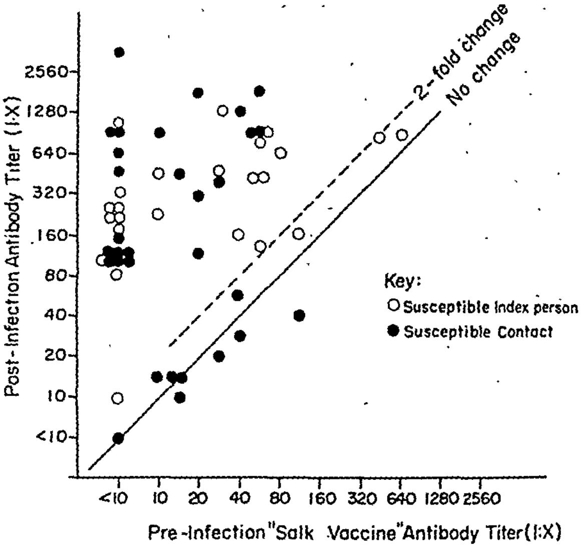
		Adult	2	0	2	1
	7.3	Child (2-5 yr.)	6	5	6	6
		Adult	1	1	2	2
2.....	5.1	Child (2-6 yr.)	5	0	6	6
		Adult	0	—	0	—
	7.1	Child (2-6 yr.)	7	4	8	8
		Adult	1	1	1	1
3.....	3.6	Child (1-2 yr.)	2	0	2	2
		Adult	0	—	0	—
	5.1	Child (3-7 yr.)	5	0	6	6
		Adult	0	—	0	—
	7.1	Child (2-6 yr.)	6	5	7	7
		Adult	1	0	1	1

Among the 46 persons who did become infected, fecal excretion was the most sensitive indicator of that fact. Pharyngeal excretion was usually detected after the administration of 7.1 to 7.3 log doses (16 of 22 persons examined), but was found after 5.1 to 5.3 log doses in only 1 of 16 persons examined. The serologic detection of infection, as indicated by a titer rise fourfold or greater, was even less reliable. Study of appropriate specimens of all persons is not yet complete, but as indicated in the figure, significant rises above the titers persisting from Salk vaccination completed one to two years previously often failed to occur where the titer before infection was greater than 1:40. It must also be added that in no instance did a significant serologic titer rise occur in any person from whose fecal specimens we failed to isolate virus. It may also be seen in table 2 that the age of the index person did not appear to affect the likelihood of infection after feeding with any given virus type or dose.



Homologous antibody titers before and after proved infection with "Sabin vaccine" in naturally susceptible persons.

The duration of excretion was very variable; demonstrable excretion from the pharynx lasted from a minimum of 2 to a maximum of 17 days and, in the feces, from a minimum of 2 to a maximum of at least 137 days. There appeared to be no relationship between this duration and either the size of the infecting dose or the age of the recipient. Table 3 shows the distributions and means of the durations

Table 3.—*Duration of Pharyngeal and Fecal Excretion of Polioviruses After Oral Administration of "Sabin Vaccine"*

	No. of Persons with Indicated Duration After Ingestion of Indicated Virus Type

* Average time elapsed between last negative specimen before excretion began and last positive and first negative specimen after excretion ended.

of excretion after ingestion of the three virus types of vaccine. (The means of the intervals between the last negative specimen before excretion began and the last positive and the first negative after it ended are given to show the equivalence of the observations.) There is a suggestion that the excretion of type 3 virus may last longer than that of the other types, although the record in this series, 137 days with no end-point being reached, was with type 1.

The incubation period of infection, as measured by the interval between the ingestion of vaccine and the onset of continuous excretion of homologous virus, was very short in the majority of index persons on whom daily observations were made. Of 11 persons in whom pharyngeal excretion was systematically sought, three were excreting virus within one day, six by the end of the second day, and in only one each was excretion first detected on the third and fifth day respectively. Of 27 persons examined daily for the presence of virus in the feces, 17 were found to be excreting within one day, nine others by the end of the second day, and in only one was onset delayed until the fifth day. There was no suggestion of a relation to virus type or dose.

Table 4.—*Homologous Infections Occurring Among Family Contacts of Index Persons Infected After Oral Administration of "Sabin Vaccine"*

* Ratio of persons infected (numerator) to family contacts present in home (denominator).

Complete series of blood specimens were collected from 16 of the susceptible index persons on days 0, 3, 7, 10, 14, 17, 20, and 60. Rise in neutralizing antibody titer, observed in 15 of these susceptible index persons, occurred between the 7th and 10th days in 12 instances, and between days 3 and 7 or 10 and 14 in two and one cases respectively. The antibody titer had clearly begun to decline between days 20 and 60 in 10 of these 15 persons.

Two susceptible index feedings are worth noting in detail. Reference has already been made to an adult who failed to become infected after ingesting 3.6 and 5.3 log doses of type 1 Sabin vaccine, but then excreted virus in the feces for five days after the administration of 7.3 log doses. It was felt that this man may have been naturally immune without demonstrable neutralizing antibody. One child was also fed more than once. After ingestion of a 3.6-log dose of type 3 Sabin vaccine, she had five days of fecal excretion but no serologic response. She was refed with a 5.1-log dose of the same type, whereupon she excreted for 29 days and experienced a marked rise in antibody titer from 1:56 to 1:800. The first infection in this child may represent the implantation of virus in so limited an area of the intestine that full evolution of the infection did not occur, and the antigenic stimulus thus was too weak. Thereafter, she remained fully susceptible, and acted as a nonimmune person on reexposure.

Infection Attempts in Naturally Immune Index Persons.—Only five naturally immune persons have so far been completely studied after ingestion of Sabin vaccine. Three of these were fed type 1 virus, and each of the others was fed type 2 or 3. All were children, and all were fed the larger dose. Three of the five failed to become reinfected. One child excreted type 1 virus in the feces for nine days, but failed to excrete from the pharynx; the child fed type 2 virus also excreted fecally for nine days, but no pharyngeal specimens were collected. Serums have not yet been tested.

Spread of Infection from the Index Person to Family Contacts.—Because of the large number of variables, any or all of which may significantly influence the spread of vaccine viruses within household units, the combination of units with identifiable differences is not fully justified. Table 4, therefore, reports the ratio of infections among naturally susceptible and naturally immune family contacts within the few units included in each category as defined by virus type, presence or absence of pharyngeal virus excretion, economic status, and family status of the index person. Since the dose of attenuated virus fed was not demonstrated to have an effect in the infected index person other than determining the likelihood of the occurrence of pharyngeal excretion, distribution of the results by dose was not tabulated. The determination of contact infection was based, in all cases, on the occurrence of fecal excretion.

Examination of this table shows a number of interesting contrasts. Among the susceptible family contacts of infected index children, many infections occurred, but there was a marked difference based on economic status, the families from the lower economic group experiencing many more. Among the three virus types of the Sabin vaccine, type 3 feedings appeared to have resulted in more spread. The presence of pharyngeal excretion may have been associated with more extensive spread than occurred in its absence, at least with types 2 and 3 virus, although a number of these contact infections apparently took place long after pharyngeal excretion had ceased. Despite the fact that the observations were few in number and restricted to families from the upper economic group, it is striking that no single instance of spread followed the infection of an index adult, even though several experienced prolonged pharyngeal excretion. Finally, the rather large number of reinfections among naturally immune persons is notable.

Table 5.—*Summary of Homologous Infections Occurring Among Family Contacts of Infected Index Children, by Economic Status and Virus Type*

All	3/28	11	19/76	25

* As in table 4.

Since differences based on economic status and virus type appeared to have been the most significant, a summary of homologous infections among the contacts of index children is shown in table 5. With the larger numbers of subjects now available, the "benefit" of lower economic status and the generally greater infectiousness of type 3 vaccine are more evident. Type 2 appears to have been the least infectious. No family contact infections resulted from the two successful feedings in naturally immune persons with types 1 and 2 viruses respectively.

The less frequent collection of stool specimens from contacts renders difficult exact statements about the interval of time between the onset of viral excretion in the index person and that in his contacts. On several occasions, however, it was as short as one day, and on others not before one, two, or three weeks. It was particularly notable that viral excretion by naturally immune persons was often greatly delayed. The infection records of two typical families from the lower economic group are reproduced in table 6.

Spread of Infection of Extra-Household Contacts.—An adequate record of specimens from persons outside the home who were in contact with Sabin vaccine-infected families is available in connection with only four study units, since extra-household studies were initiated only where conditions for spread were likely to be optimal, i. e., with the administration of 7 log doses in lower economic families. In one of these units, neither the two siblings within the family nor the one susceptible extra-household child contact became infected with type 2 poliovirus, despite prolonged fecal excretion by the index child and frequent, intimate contact.

The second of the units studied was remarkable in that a single 2-hour period of contact, confined exclusively to the type 3–infected index child, resulted in the infection of two out of three child visitors. The third unit is in some contrast in that a similar two-hour contact period between three child visitors and the four infected children in the family studied resulted in only one infection. The two who missed infection had the same limited opportunity two weeks later and again escaped.

A special study was planned around a fourth unit which was intended to initiate a long series of passages from one household to another, among a group of cooperative, related families. The index child was fed type 3 Sabin vaccine and then removed from all play contact, except with her siblings; on infection of the four siblings, only the latter were permitted to associate with the extra-household families. The second link in the intended series was a large family containing five susceptible cousins. Unfortunately, this passage failed completely, despite frequent and intimate play contact, perhaps because of interference by coincidental natural episodes of ECHO type 1 and poliovirus type 2 involving four of the five type 3–susceptible children in the exposed household. However, three of the four other extra-household contacts in three households did contract infection with type 3.

Nature of the Infection Experienced by Contacts.—Only on a single occasion was homologous virus isolated from the pharyngeal specimen of a contact. The distributions and means of the durations of fecal homologous polioviral excretions, by contacts of persons ingesting Sabin vaccine, are indicated in table 7.

The significance of the shorter mean duration of type 1 excretion is doubtful, in view of the great variation among individuals and the small numbers involved. Of greater import is the rather large number of contact persons who excreted for very short periods of time, and who were therefore unlikely to be able to spread their infections to others. This is particularly characteristic of those naturally immune, but is also true of a substantial proportion of the naturally susceptible contacts. Since all of the persons who excreted for only one day also failed to experience a booster rise in high-avidity antibody titer, and since, in many instances, fecal specimens were not obtained daily from contacts (table 6), it is quite likely that a number of contact infections with only brief viral excretion were missed. It is interesting, nevertheless, that the mean duration of excretion of all three types among susceptible contacts (24.3 days) was very close to the same mean among susceptible index persons (28.2 days).

The likelihood of detecting a titer rise after proved infection in those persons who had preexisting antibody derived from Salk vaccine was previously discussed and illustrated in the figure. The more frequent absence of rise from low initial titer in infected contacts, as compared with infected index persons, is notable and related to the frequency of transient infections in the contacts. Among the 14 naturally immune persons in whom infection was observed and whose serums have been studied, no rise in titer could be demonstrated.

[§] On 13th day homologous poliovirus was isolated from kitchen floor.

Coincidental "Wild" Enteroviral Infections.—Since many of the family units of study were being investigated during the summer and autumn months, and since New Orleans is an area of high enteroviral endemicity, it is not surprising that several episodes of infection with other enteric viruses occurred coincidentally with the administration of the Sabin vaccine: poliovirus type 2, ECHO virus types 1, 6, and 9, Coxsackie virus types A9 and B5, and an unidentified agent with adenovirus-like cytopathogenicity. On several occasions, interference between these agents and attenuated strains being fed was strongly suggested. Table 8 gives three examples. In unit 10, Coxsackie B5 was infecting all three susceptible children at the time when type 1 Sabin vaccine was fed to the 5-year-old. The large dose administered may have suppressed further multiplication of the Coxsackie virus in the index child, but the smaller dose received by the others by way of "normal" contamination appears not to have been sufficient, and they escaped "vaccination." Unit 15 may illustrate reciprocal interference between a "wild" type 2 and the attenuated type 1 virus. At a later time, after both types had disappeared from the family, the index child became infected with type 2, perhaps from a neighborhood source outside the home. In unit 46, an ECHO type 1 episode was either just beginning or nearing termination in the household when the index child was fed with attenuated type 3 Sabin vaccine. The ECHO infections spontaneously disappeared or were suppressed by the spreading attenuated poliovirus, and eventually all susceptible children became infected. In addition to other episodes similar to the above, many casual infections with enteroviruses, including an ECHO 9 isolation from a pharyngeal gargle, were detected later during the course of unit investigations, when interference could not be postulated.

Virus Recovery from the Skin and from Fomites in Households.—During the course of the investigation of 26 study units, some attempt was made to detect the presence of homologous poliovirus from sites other than the pharyngeal or fecal excretions during that period after vaccine administration when the virus was circulating widely among family members. This effort was opportunistic, not carefully organized, and was made in those households with the poorest hygienic standards where the likelihood of environmental contamination was greatest. The places examined by swabbing included most commonly the skin of the hands, feet, and buttocks (excluding the perianal area) of an index child or his infected siblings, toys, floors, and doorknobs.

Table 7.—*Duration of Fecal Excretion of Homologous Polioviruses by Family Contacts of Persons Fed "Sabin Vaccine"*

* As in table 3.

In five study units a poliovirus was recovered. In one instance the homologous type 2 was collected from the buttocks of the index child, and in two other instances the homologous type 3 was found on the buttocks of an infected sibling or on the kitchen floor. In a fourth unit, the homologous type 3 was recovered from the hands of the index child in four separate attempts on different days. The fifth instance is most interesting in that in a family fed Sabin vaccine type 1, which experienced a coincidental "wild" type 2 poliovirus infection, only the latter virus was found in a swab of the living room floor.

Illness Associated with Infection with Attenuated Vaccine Viruses.—Despite intensive and leading questioning, no evidence could be found to suggest that any illness, however minor, could be related to the infections produced by the administration or spread of the vaccine virus strains.

Comment

Although the primary object of this still-continuing investigation was the study of the transmission of infection with the attenuated poliovirus vaccine strains of Sabin, the results relative to primary infection in the vaccine recipient are of interest. With oral inocula consisting of approximately 100,000 infectious units, the dose recommended by Sabin for routine use, all of the three strains considered were able to initiate infection in all but one of the presumably susceptible persons. However, pharyngeal infection after administration of doses of this size was exceptional, in contrast to the usual appearance of virus in the throat after a larger inoculum containing somewhat more than 10 million viral particles. A dose of 4,000 units of type 1 virus failed to infect four persons to whom it was given, and an equal dose may have been on the border line of infectivity with type 3. All of the foregoing suggests that the infectivity of the attenuated strains must be considerably less than that of "wild" strains. This is consistent, moreover, with the greatly reduced intrafamilial dissemination of the attenuated strains, as compared with the results of studies of natural poliovirus infections with the same and similar families [11] in which more than 90% of susceptible persons became infected.

After infection in the recipient, however, the sequence of events, in terms of the duration of pharyngeal and fecal excretion of virus and of serologic response, greatly resembles that which follows natural infection in Salk-vaccinated persons. Unfortunately, titrations of virus in fecal extracts have not yet been made. The failure of many persons to manifest an antibody rise, especially if the preinfection titer derived from formalinized vaccine is greater than 1:40, should be re-emphasized, since this phenomenon renders invalid studies based exclusively on serologic examination. The rise in antibody titer, when it did occur, between the 7th and 10th day after ingestion in the majority of persons,

does not suggest that the previous sensitization with Salk vaccine had produced an accelerated response, although comparable studies in unvaccinated persons were not done.

Among the 46 family units in which spread of virus from a vaccine-induced infection was studied, the more readily identifiable variables were virus type, virus dose, and the related pharyngeal excretion of virus, socioeconomic status, and age of the index person. Perhaps of at least equal importance in influencing viral transmission are concurrent infections with other enteric viruses and subtle variations in the interpersonal relationships of the individuals comprising these families. Because of the multiplicity of variables and the small numbers of units per identified variable, conclusions as to the influence of individual factors in predisposing to or limiting transmission seem justified only if the results are definite and consistent.

Among the three virus types, there is a suggestion that type 3 ordinarily may spread more readily than either of the others; however, in individual instances, both types 1 and 2 viruses infected all of the contacts. A direct effect of virus dose was not noted, but the larger (7 log) doses resulted in a greater proportion of index pharyngeal excretors, who in turn were associated with more extensive transmission of types 2 and 3. However, the significance of this is weakened by the fact that development of infection of some contacts appeared well after pharyngeal excretion had ceased. Since fecal extracts have not yet been titrated, some association between virus titer in the feces and viral multiplication in the throat cannot be ruled out. Moreover, a possible effect of the larger dose on suppressing or aborting coincidental "wild" virus infections has not been evaluated. Nonetheless, although pharyngeal excretion may have some effect in increasing the probability of virus transmission, the demonstration that spread occurs readily in its absence is of much greater import. This relates to the suggestion by Salk [12] that, if formalinized vaccine reduces pharyngeal multiplication, and if the transmission of poliovirus is by way of pharyngeal excretions in a well-sanitated population, then the widespread use of a formalinized vaccine may reduce the volume of transmission in such a community. Spread certainly did occur in many of these Salk-vaccinated families in the demonstrated absence of pharyngeal excretion of virus. Furthermore, spread of infection did not occur among several families from the upper economic group in which the index person was a mother who was excreting virus from the throat.

The one variable which definitely played a role in controlling the extent of intrafamilial transmission was socioeconomic status. Only 9% of susceptible contacts from the upper economic group became infected as contrasted with 53% among households from the lower economic group. This is a much greater difference than was seen in episodes of natural poliovirus transmission where the infection of almost all susceptible contacts is the rule, regardless of sanitary status. This probably is to be explained by the lesser infectivity of the attenuated strains.

The demonstration of transmission of vaccine viruses outside the family unit to play contacts suggests the possibility that an entire community might be saturated with these strains, if they were administered to a sufficiently large proportion of the susceptible children present. Despite their lower infectivity, the multiple opportunities for contact then available might enable them to compete effectively with other, "wild" strains present in the population, eventually, perhaps, to displace them.

Interference between enteroviruses has been demonstrated often in the laboratory, and has been postulated as an explanation for some peculiarities in the occurrence of epidemics of poliomyelitis and pleurodynia.[13] If this is a phenomenon which occurs under natural conditions, we might expect that the introduction of a related enteric virus into a household coincidentally with the administration of an attenuated strain might inhibit the spread of the latter, as is strongly suggested in certain of our unit studies. Thus, while, in practice, extensive community spread of vaccine polioviruses may be limited in good environments by superior hygienic standards, it may, rather paradoxically, be limited by viral interference in poor environments. If such interference takes place commonly, it might be of great importance in limiting the effectiveness of mass live-virus immunization programs in poorly sanitated areas.

Finally, the total absence during this study of harmful effects consequent to infection with these living, attenuated poliovirus strains is to be noted. Although the persons taking part were few in number, these results may be added to the rapidly growing record of safety which is being accumulated for this method of immunization against poliomyelitis.[9]

Summary

A study of the spread of infection with Sabin's living, attenuated strains of polioviruses was conducted in 56 "Salk-vaccinated" household units in New Orleans. Each unit contained at least three naturally susceptible members, one of whom was fed the oral vaccine. The course of infection in this index person was followed by virologic and serologic means, and spread to other persons within and without the families was similarly studied. The effect of such variables as virus type, virus dose and the related excretion of virus in the pharynx, socioeconomic status, and age of the vaccine recipient was investigated. All except one adult became infected after the feeding of at least 100,000 infectious units, and transmission to many contacts was detected. Socioeconomic status appeared to have the most marked effect on spread, upper status usually

being associated with failure of transmission. Interference to spread of the attenuated strains by other, "wild" enteric virus infections among families from the lower economic group was strongly suggested. No illness was associated with either primary vaccine administration or contact infection.

HUMAN PHARMACOLOGY OF THIAZIDE DERIVATIVES

John H. Moyer, M.D., Philadelphia

Chlorothiazide in doses of 1 Gm. by mouth twice daily induced the excretion of practically the same amounts of sodium and chloride as did 2 cc. of a molar solution of meralluride injected intravenously. When the chlorothiazide was administered daily for two or three weeks, the sodium excretion declined until it approached the daily intake, and the patient's body weight approached a steady level about 4 lb. (1.8 kg.) below the initial level. A nearly maximal rate of sodium excretion was obtained with 2 Gm. of either chlorothiazide or flumethiazide, and increasing the doses to 4 Gm. did not yield further significant increases of sodium excretion. For hydrochlorothiazide the dose required to give maximum excretion rates was 200 mg. A steadier effect and over-all increase in response resulted from giving doses of 200 mg. of hydrochlorothiazide every 12 hours as compared to 400 mg. given once a day.

Numerous clinical conditions of diverse etiology are associated with sodium and water retention, due usually to increased reabsorption by the renal tubules. Because of the varied causes of edema, a drug, if it is to be effective, must be adequately potent to depress the reabsorption of sodium and water irrespective of the etiology of the retention.

Chlorothiazide (Diuril) is an effective natruretic and diuretic agent when administered orally, and it compares favorably with the organomercurials which are given parenterally. As in the case of the organomercurials, the increase in water excretion is secondary to the natruresis. Although the incidence of serious side-effects after the administration of chlorothiazide is low, a number of derivatives of chlorothiazide have been developed in an effort to find more potent compounds with fewer side-effects. This report presents certain pharmacological properties of chlorothiazide and two of its derivatives,

flumethiazide (Ademol) and hydrochlorothiazide (Hydrodiuril), placing particular emphasis on the response in electrolyte excretion.

Effect on Electrolyte Excretion

Chlorothiazide inhibits carbonic anhydrase in vitro, being more active than sulfanilamide but less active than acetazolamide (Diamox).[1] In vitro, chlorothiazide exerts its effect primarily in the renal tubules. Some investigators[2] propose that chlorothiazide produces its diuretic response by inhibition of sodium and chloride reabsorption, with subsequent exchange of some of the sodium for potassium in a more distal portion of the tubule, resulting in a moderate increase in potassium excretion. These authors also compared chlorothiazide and meralluride (Mercuhydrin). They concluded that chlorothiazide acts more distally in the renal tubule than meralluride. Presumably flumethiazide and hydrochlorothiazide have the same action.

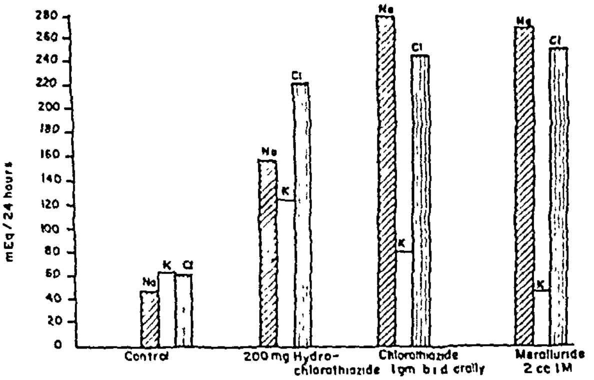

Fig. 1.—Effect on sodium, potassium, and chloride excretion of hydrochlorothiazide as compared to chlorothiazide and meralluride.

Chlorothiazide and the two derivatives (hydrochlorothiazide and flumethiazide) produce effects within 2 hours after oral dosage that reach a maximum within 6 hours; the response persists for 12 hours or more. The primary effect of chlorothiazide is an increase in sodium excretion, with a slightly lesser effect on chloride excretion (fig. 1). There is a moderate and consistent increase in potassium excretion. As a compensatory renal mechanism to conserve sodium, ammonia excretion is increased during the second 12-hour period but shows no increase before that. The increase in the rate of excretion of bicarbonate is about one-fourth that of chloride. Phosphate excretion is not altered. By contrast, a carbonic anhydrase inhibitor such as acetazolamide produces an immediate augmentation of sodium excretion, with an almost equal effect on potassium and bicarbonate excretion. Acetazolamide suppresses chloride excretion during the period of greatest bicarbonate loss, but the former increases when the latter subsides. Phosphate excretion is not affected by carbonic anhydrase inhibitors.

In general, the spectrum of activity of chlorothiazide appears to resemble that of the mercurial agents. As with administration of the thiazide derivatives, the administration of meralluride parenterally is followed by an onset of action within one hour which reaches its maximum in 2 to 6 hours, and the natruretic effect lasts for 12 to 18 hours. An increased excretion of sodium and chloride is the predominant effect,[3] while potassium excretion is not significantly altered (fig. 1). Ammonia excretion, slightly depressed at first, becomes elevated after the period of greatest sodium loss. During the stage of greatest chloride loss, bicarbonate excretion is suppressed, but this returns to normal or higher when the chloruretic response subsides.

The predominant effect of chlorothiazide and flumethiazide is to increase sodium excretion, with a lesser but nearly equal effect on chloride excretion. By contrast, the predominant effect of hydrochlorothiazide is to increase chloride excretion, with a lesser effect on sodium (fig. 1).

Ford[4] compared the response to chlorothiazide given alone and in combination with meralluride or the carbonic anhydrase inhibitor acetazolamide. With the former combination, the response was additive. With the latter combination, the maximum chloride output was only one-half that of sodium and the bicarbonate loss was fourfold to sixfold greater than that which occurred when chlorothiazide alone was given.[4] There was a modest increase in sodium excretion. It appears from both preclinical and clinical studies that the effects of chlorothiazide on sodium excretion are additive to those of mercurial diuretics as well as to the response to carbonic anhydrase inhibitors. It is quite possible that chlorothiazide shares a common mechanism of action with meralluride and another with acetazolamide but that it also acts through a third, noncompetitive mechanism.[5]

Both meralluride and the thiazide derivatives reverse the effects of vasopressin (Pitressin), which normally decreases urine flow but does not alter the rate of electrolyte excretion. When chlorothiazide or meralluride is given to dogs who have previously received vasopressin, the urine flow is increased and sodium, potassium, and chloride excretion rates are greatly increased also. The urine is hypertonic with respect to both sodium and chloride, suggesting that the effect is at least partly attributable to a direct influence of chlorothiazide on renal tubular electrolyte transport.

Chlorothiazide also reverses the inhibitory effect of various steroids on salt excretion. When cortisone, hydrocortisone, or fludrocortisone is given to adrenalectomized dogs, sodium excretion is suppressed and potassium excretion is augmented; consequently, the sodium-potassium ratio declines. When chlorothiazide is given at this stage, the sodium excretion increases considerably, with an accompanying small increase in potassium excretion. The relatively greater increase in sodium output tends to raise the sodium-potassium ratio toward normal. Similar observations have been made on patients who were receiving steroids therapeutically.

With continuous daily administration, chlorothiazide has repetitive action (fig. 2). Increased sodium excretion continues until body stores of sodium have been reduced (fig. 2). Serum concentrations of chloride and potassium are slightly depressed, while that of bicarbonate is slightly elevated. The natruretic effect of mercurials is qualitatively similar to that of chlorothiazide. The trend toward hypochloremic alkalosis is sometimes observed with the administration of thiazide derivatives, especially hydrochlorothiazide.

Observations on Renal Hemodynamics

Doses of 0.5 mg. and 10 mg. of chlorothiazide per kilogram of body weight given intravenously appeared not to have a significant effect on mean blood pressure. Glomerular filtration rate was not affected by the 0.5-mg. dose, but after the 10-mg. dose it was slightly depressed, probably as a response to the water and sodium loss (dehydration phenomenon) associated with the diuresis.[3a] It is not likely that chlorothiazide inhibits the renal tubular extraction of para-aminohippurate, since para-aminohippurate clearance was not reduced at the time that chlorothiazide exhibited its maximum effect. In conclusion, the diuretic response to chlorothiazide cannot be attributed to an increase in glomerular filtration rate, indicating that the diuretic response results from blockade of water and electrolyte reabsorption in the renal tubules.

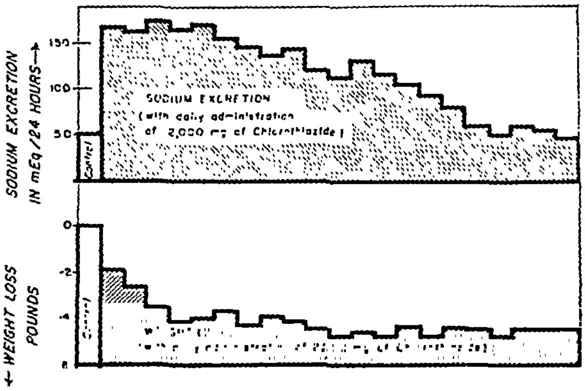

Fig. 2.—Effect of continuous administration of chlorothiazide on sodium excretion and weight loss in patient with minimal edema. After two to three weeks' daily therapy, sodium excretion approximates intake. This occurs as the body stores become depleted. Despite this approximation, weight loss is maintained.

Similar observations have been made on flumethiazide. When 800 mg. of flumethiazide was given orally to patients in heart failure, there was a sharp increase in sodium excretion one hour after the drug was given (fig. 3), and this persisted throughout the period of observation (five hours). There was no effect on mean blood pressure, glomerular filtration rate (fig. 4), or renal plasma flow. Despite the marked natruresis, plasma sodium and potassium concentrations were not altered.

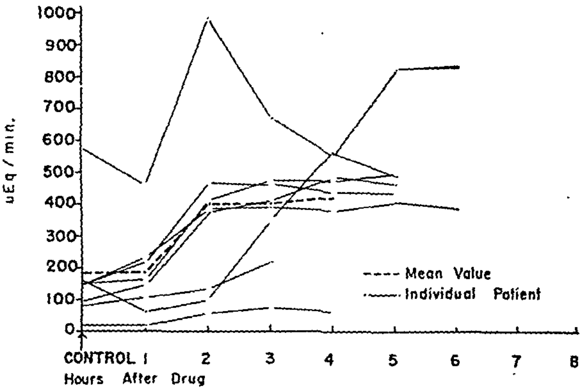

Fig. 3.—Effect of flumethiazide on sodium excretion after single dose of 800 mg. given orally.

Observations on hydrochlorothiazide likewise showed no significant alteration in renal hemodynamics after the administration of 100 mg. orally. When 200 mg. was given intravenously, there was a temporary reduction in glomerular filtration rate which returned to control levels within one hour after the drug was given.

Bioassay Studies

Dose response curves, with sodium excretion used as the critical modality, were determined for patients who were on a controlled sodium intake. Since the patients were in electrolyte balance on a diet containing 50 mEq. of sodium, the control excretion in the urine was approximately 90% of the dietary sodium (about 45 mEq.). The average increase in the 24-hour urinary sodium excretion after chlorothiazide was 44 mEq. after the 500-mg.

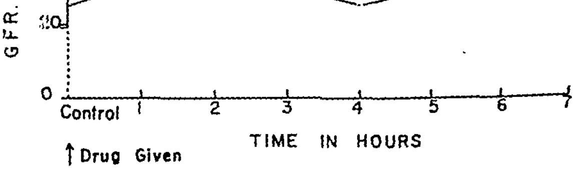

Fig. 4.—Effect of single 800-mg. oral dose of flumethiazide on glomerular filtration rate. Lines indicate responses of individual patients. There was no evidence of significant increase or reduction in glomerular filtration rate within six hours after administration.

dose and 104 mEq. after the 2,000-mg. dose (fig. 5). There was no additional natruresis when the dose was increased above 4 Gm. and very little increase when the dose was increased from 2 to 4 Gm. (fig. 5). Similar observations were made when flumethiazide was administered (fig. 6). The curve of response to hydrochlorothiazide is shifted to the left. A significant increase in sodium excretion starts at the 25-mg. dose and increases to a maximum at the 200-mg. dose level (fig. 7). This appears to be the maximum effective dose level, and no further increase in sodium excretion is produced by a dose larger than 200 mg. The chloruretic response was noticeably larger than the natruretic response, and potassium excretion was approximately one-half that of sodium. At maximum responses for chlorothiazide and hydrochlorothiazide, the increase in sodium excretion was the same, although the dose required to produce this maximum effect with hydrochlorothiazide was only about 10% of that required with chlorothiazide.

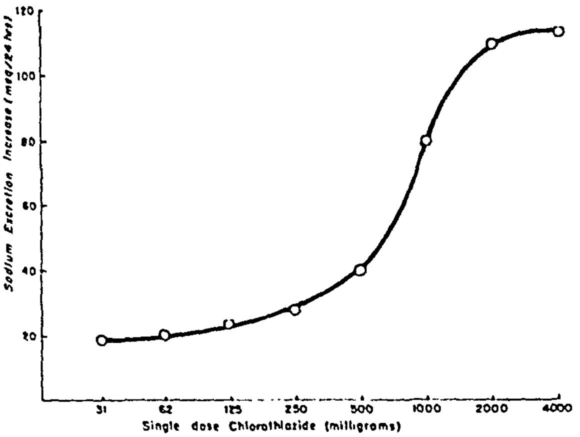

Fig. 5.—Curve of response to chlorothiazide, with increase in sodium excretion used as reference point. Minimal effective dose appeared to be between 125 and 250 mg. Dose which produced maximum increase in excretion was about 2,000 mg. Increase was not significant when dose was increased from 2,000 to 4,000 mg. (Reproduced from Ford and others: A. M. A. *Arch. Int. Med.* **100:**582 [Oct.] 1957.)

When potency of chlorothiazide is compared with that of other diuretics, it appears that a dose of meralluride (1 cc.) equivalent to 40 mg. of mercury produces an increase in sodium excretion that is equivalent to about 1,000 mg. of chlorothiazide administered orally, and 700 mg. of chlorothiazide is equivalent to 1 cc. of mercaptomerin (Thiomerin) administered parenterally. When both drugs are administered orally, four tablets (equivalent to 40 mg. of mercury) of chlormerodrin (Neohydrin) are equivalent in natruretic potency to 560 mg. of chlorothiazide. The response to flumethiazide is about the same at equal doses. The response to hydrochlorothiazide is also about the same, but at 10% of the dose of chlorothiazide.

To determine differences in sodium and potassium excretion for chlorothiazide given as a single dose and as fractional doses per 24 hours, the sodium and potassium excretion was observed in a patient who received 4,000 mg. as a single dose at 6 a. m. After a suitable recovery period (seven days) the drug was given as 1,000 mg. every six hours for four doses. There was a greater potassium loss on the fractional dose schedule. However, there was an even greater sodium loss, indicating the advantage of fractional doses. Similar observations have been made with flumethiazide and hydrochlorothiazide (fig. 8).

Nervous System Effects

Chlorothiazide appears to be free of actions on the nervous system. Consequently, it does not have appreciable antiepileptic, anesthetic, analgesic, or antiglaucomatous effects. Unlike acetazolamide, it apparently does not penetrate the blood-brain barrier and is consequently not distributed through the central nervous system in appreciable concentration. For this reason it produces little effect referable to the central nervous system.

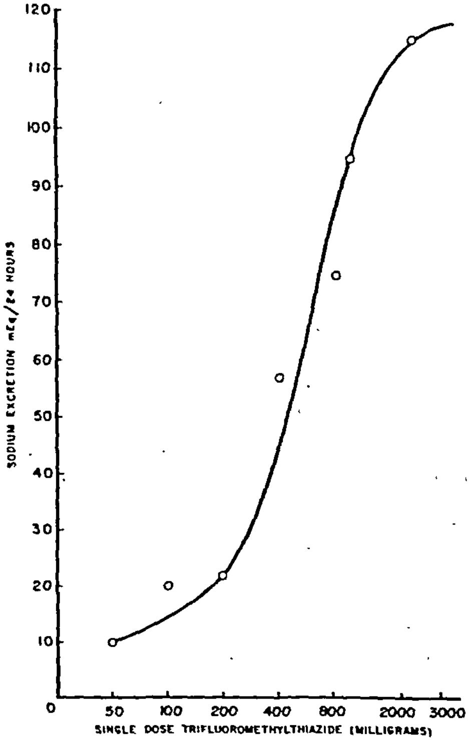

Fig. 6.—Curve of response to flumethiazide (trifluoromethylthiazide). Curve is similar to that observed after administration of chlorothiazide (fig. 5).

Evidence indicates that chlorothiazide, even in large intravenous doses, has no significant effect on the cardiovascular-respiratory system of anesthetized dogs. Cardiovascular effects of injected acetylcholine, histamine, epinephrine, and nicotine were unaltered by chlorothiazide, as was the reflex pressor effect of central vagal stimulation. No effect was noted on mean arterial blood pressure or heart rate. These findings indicate that the drug does not possess significant antihistaminic, adrenergic-blocking, atropine-like, or ganglionic-blocking activity.

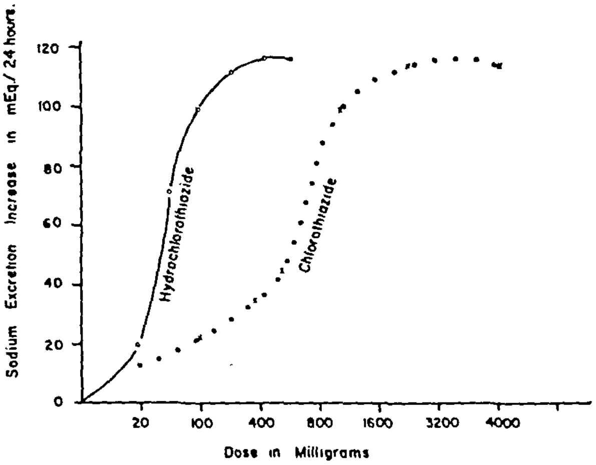

Fig. 7.—Dose-response curve for hydrochlorothiazide as compared to chlorothiazide. Curves were similar but with smaller dose of hydrochlorothiazide. However, greater increase in sodium excretion could not be obtained by its administration. Maximum effective dose of hydrochlorothiazide appeared to be about 200 mg. and that of chlorothiazide was about 2,000 mg.

Clinical Use

The initial dosage of chlorothiazide and flumethiazide in edematous subjects is 1 to 2 Gm. daily, and for hydrochlorothiazide it is 100 to 200 mg. daily for three to five days or until overt edema disappears. This is followed by administration of a maintenance dose of 250 mg. to 1.0 Gm. of chlorothiazide and flumethiazide and 25 to 100 mg. of hydrochlorothiazide daily. Total daily amounts of over 500 mg. of chlorothiazide and flumethiazide and 50 mg. of hydrochlorothiazide are customarily given in two divided doses at 8-to-12-hour intervals. Since these compounds exhibit a rising dose-response curve,[3b] the dosage should be adjusted to the needs of the patient. Therapy in severely ill patients is started at higher dosage levels than in those with moderate or mild edema. The dosage and frequency of administration should be readjusted subsequently according to the patient's response.

In mild or moderate edema, smaller doses and intermittent administration, for two or three days per week, may be preferable. Occasionally even severely ill patients will respond better to intermittent administration (three days per week).

For premenstrual tension, therapy with 500 mg. of chlorothiazide or flumethiazide or 50 mg. of hydrochlorothiazide daily is usually started five to seven days before the period and discontinued at the onset of menses. In edema of pregnancy, with or without hypertensive vascular disease, similar daily doses for five days per week are recommended. Lower doses have failed to produce sufficient initial diuresis.

When the thiazide derivatives are first administered to hypertensive patients being treated with other drugs, it is advisable to continue giving Rauwolfia derivatives in the standard dosage and to reduce the dose of the other agents (fig. 9). The dose particularly of the ganglionic-blocking agents should be reduced one-half or more (to avoid a possible precipitous fall in blood pressure), and then it should be increased or decreased in small increments according to the patient's response. Careful, repeated observations of blood pressure, *especially during initial therapy*, are essential. Doses of chlorothiazide and of other antihypertensive drugs given simultaneously can sometimes be further decreased, once the blood pressure becomes stabilized at the lower level.

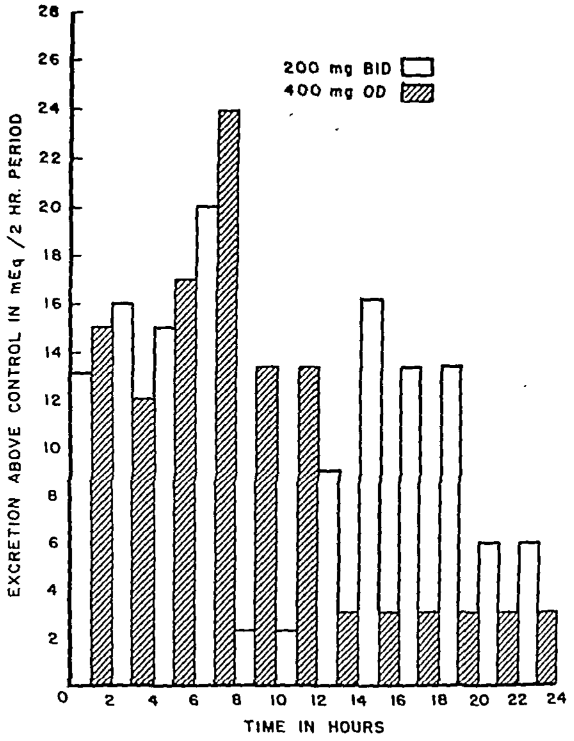

Fig. 8.—Natruretic response to hydrochlorothiazide, 200 mg. every 12 hours as compared to 400 mg. given once a day. Although there was somewhat larger response initially to 400-mg. dose, significant increase in excretion occurred when second 200 mg. was given in twice-a-day regimen.

Therapeutic Precautions

Edema syndromes, particularly heart failure, may be associated with electrolyte abnormalities. Some of these are due to coexistent gastrointestinal, hepatic, renal, or pulmonary disturbances, while others may be the result of intensive or excessive use of therapeutic agents. These electrolyte disturbances may cause serious symptoms and may also render the underlying disease unresponsive to therapeutic regimens. An electrolyte imbalance should be suspected (and confirmed by chemical studies) in all patients whose conditions become refractory to diuretic agents. However, when careful appraisal shows that both symptoms and electrolyte disturbances arise from progression of the underlying disease, diuretic therapy will probably be of no avail. Electrolyte disturbances caused by vigorous diuretic therapy, on the other hand, can usually be readily corrected.

Hypochloremic alkalosis may be avoided by a judicious adjustment of the dosage and frequency of administration of thiazide derivatives and by avoidance of rigid salt restriction. This side-effect is most likely to occur in association with the administration of hydrochlorothiazide, since the primary effect of this agent is to increase chloride excretion rather than sodium excretion. This response is in contrast to that with the other thiazide derivatives. Temporary cessation of drug therapy or the administration of ammonium chloride prevents or corrects the alkalosis if it does occur. The therapist should remember that, in patients with hepatic insufficiency, ammonium salts can produce ammonium intoxication. The low-salt syndrome as a complication of therapy with the thiazide compounds does occur occasionally. When the history and blood electrolyte studies establish the fact that sodium depletion is present, salt can be given by mouth or a cautious infusion of hypertonic sodium chloride may be used. Water should rigidly be restricted while the infusion is being given and for three to six hours thereafter. Diuretic therapy is usually discontinued until the reestablishment of a normal or nearly normal blood electrolyte pattern.

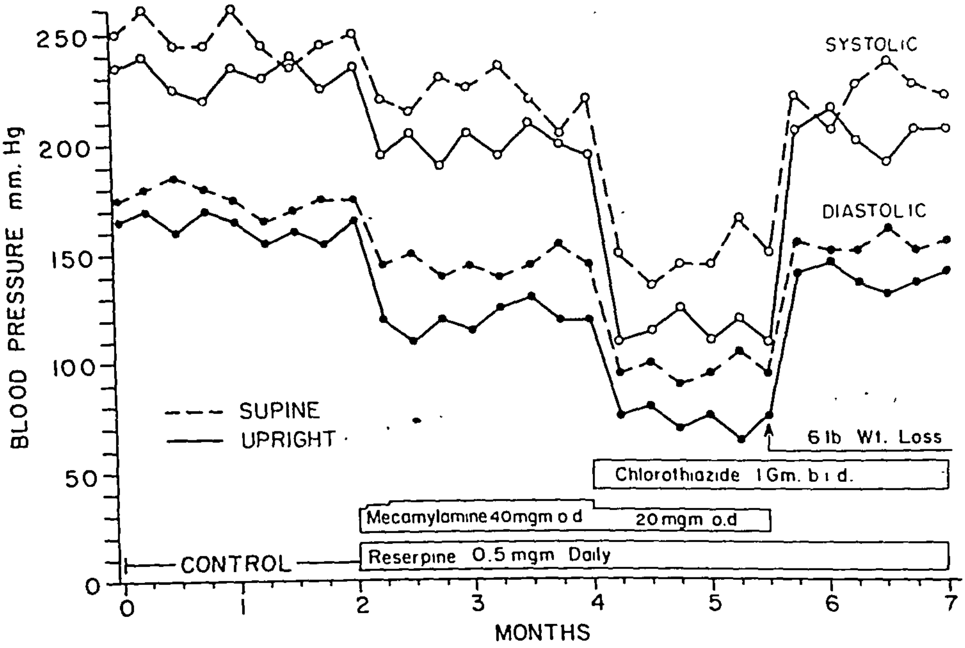

Fig. 9.—Effect of chlorothiazide on blood pressure response to rauwolfia and ganglionic-blocking agent in hypertensive patient with left ventricular strain. Even with one-half the original dose of blocking agent, reduction in blood pressure was much greater than that observed while patient was taking rauwolfia and mecamylamine without diuretic. (Reproduced with permission from *Ann. New York Acad. Sc.* **71**:456, 1958.)

Intensive or prolonged administration of chlorothiazide and its derivatives may produce hypokalemia. Mild depression of serum potassium level usually produces no symptoms. As the potassium deficit accumulates, gradual diminution of strength is noted; the muscles tend to become flaccid and the reflexes, hypoactive or absent. The patient may complain of weakness only, or of numbness of the extremities. When the hypokalemia is severe, symptoms include apathy, drowsiness, anorexia, nausea, paralytic ileus, hypotension, and shallow, infrequent respiration. Hydrochlorothiazide is more likely to produce potassium depletion (hypokalemia) than are chlorothiazide and flumethiazide.

Significant electrocardiographic changes may appear when the serum potassium level drops to 3 mEq. per liter or lower. These are prolongation of Q-T interval due mainly to flattening and widening of the T wave, T-wave inversion, and depression (sagging) and low "take-off" of the S-T segment. These changes may occur independently or in combination.

Hypopotassemia sensitizes the myocardium to the action of digitalis and may result in digitalis toxicity. This is indicated by cardiac arrhythmias, most often paroxysmal auricular tachycardia with block. Treatment consists of omitting digitalis and administering potassium, preferably orally, care being taken not to bring on potassium intoxication.

Prophylactic administration of potassium chloride or citrate (1 to 6 Gm. daily) along with chlorothiazide is particularly recommended in patients with conditions which may be associated with potassium deficiency, especially with fever or when excessive loss (with diarrhea) is imminent. Potassium deficiency may also develop during the administration of some adrenocortical steroids.

Conclusions

In the final analysis, diuretic therapy is only one important facet of the management of edematous patients. An effort must always be made to correct the underlying abnormality when specific therapy is available.

ACUTE PANCREATITIS IN PATIENTS RECEIVING CHLOROTHIAZIDE

David H. Johnston, M.D.

and

Allen L. Cornish, M.D., Lexington, Ky.

Acute pancreatitis was diagnosed in three women, all 50 years of age or older, who had been taking 0.5 to 1.0 Gm. of chlorothiazide daily for two or three months in the course of treatment for cardiovascular disease. In no case was there a history of conditions usually considered as predisposing to acute pancreatitis. The diagnosis was based on both clinical and laboratory studies and was confirmed in one case by histological study of autopsy material. Although the specific etiology remained undetermined, chlorothiazide was considered as a possible cause. The authors wish to alert physicians to this possibility, which may warrant further investigation.

Chlorothiazide, since its introduction in 1958, has gained widespread acceptance as an effective and relatively safe diuretic and antihypertensive agent. Undesirable effects occurring after the use of chlorothiazide have been largely those resulting from electrolyte disturbances. These disturbances actually reflect exaggerated therapeutic responses and are not true reactions of toxicity. However, there have been scattered reports of direct toxic effects, such as papular skin rashes,[1] exfoliative dermatitis,[2] purpura,[3] and jaundice.[4] In our experience, as well as that of others, such toxic effects are extremely rare; however, within the past year we have observed the development of severe acute pancreatitis in three patients who had been taking chlorothiazide daily for several months. These patients did not have any of the usual precipitating causes of acute pancreatitis, such as associated cholecystic disease, pancreatic tumor or infection, injury to the pancreas, or alcoholism. It seems timely, therefore, to call to the attention of others the possibility that pancreatitis may be a complication of chlorothiazide therapy. A report of these three cases follows.

Report of Cases

CASE 1.—The patient was a 78-year-old widow who had severe arteriosclerotic heart disease. Control of her symptoms of congestive heart failure had required salt restriction, digitalis therapy, and injections of meralluride three times per week. On Jan. 7, 1958, the meralluride therapy was discontinued and the administration of 1 Gm. of chlorothiazide daily was begun. The digitalis therapy was continued, but no other medicaments were given. Satisfactory control of the congestive heart failure ensued and the patient noted that taking the chlorothiazide daily freed her from the "ups and downs" of intermittent mercurial diuresis.

From the Division of Medicine, Lexington Clinic.

At 4 a. m. on April 1, 1958, she was awakened by severe abdominal pain and repeated vomiting. She was seen shortly thereafter at home. Physical examination revealed an acutely ill, cyanotic, elderly female in severe distress. The skin was cold and moist. The cardiac sounds were of fair quality, the rate was 72 beats per minute, and the rhythm was completely irregular. The lungs were free of rales. The abdomen was distended and silent; tenderness was present in the epigastrium and right upper quadrant. Results of rectal and pelvic examinations were negative. The peripheral pulsations were intact.

The patient was admitted to the hospital later that morning. Laboratory studies done about seven hours after the onset of her pain revealed an erythrocyte count of 4,930,000 and leukocyte count of 21,000 per cubic millimeter of blood, with 87% neutrophils, of which 11% were band forms. The concentration of hemoglobin was 14.2 Gm. per 100 cc. of blood. Results of urinalysis were negative. The serum amylase level was 1,630 units per 100 cc. A plain roentgenogram of the abdomen revealed a few gas-containing loops of small intestine but no free air or abnormal calcifications.

The diagnosis of pancreatitis was obvious, and the patient was treated with sedation, administration of atropine, nasogastric suction, and fluid replacement. On the third hospital day the serum amylase level was 562 units per 100 cc. However, the patient's condition steadily worsened, and 75 hours after the onset of abdominal pain she died. Postmortem examination revealed severe hemorrhagic pancreatitis with widespread fat necrosis. The liver, gallbladder, and bile ducts were normal.

Case 2.—The patient was a 52-year-old married female who had had moderately severe hypertensive vascular disease for several years. Two years previously she had had an acute cerebrovascular accident resulting in a spastic right-sided hemiparesis. Her blood pressure had ranged from 190 to 250 mm. Hg systolic and from 118 to 120 mm. Hg diastolic. On July 14, 1958, her blood pressure was 210 mm. Hg systolic and 130 mm. Hg diastolic. At that time the administration of 5 mg. of mecamylamine and 500 mg. of chlorothiazide daily was begun.

On Nov. 6, 1958, the patient was admitted to the hospital because of severe abdominal pain, nausea, vomiting, weakness, and polyuria. Physical examination revealed a confused, drowsy, dehydrated, obese woman. Her blood pressure was 190 mm. Hg systolic and 115 mm. Hg diastolic. The cardiac rate was regular and the heart was of normal size, but there was a grade 1 systolic apical murmur. Examination of the ocular fundi revealed grade 2 hypertensive changes. Dental caries and marked periodontoclasia (pyorrhea alveolaris) were present. The abdomen was distended, tender, and silent. The concentration of hemoglobin was 16.6 Gm. per 100 cc. of blood. The erythrocyte count was 6,100,000 and the leukocyte count 10,800 per cubic millimeter of blood, with 87% segmented neutrophils, 5% band neutrophils, 7% lymphocytes, and 1% monocytes. The sedimentation rate was 49 mm. in one hour (Westergren method). Urinalysis revealed a specific gravity of 1.028, glycosuria (4+) and acetonuria (2+). Results of microscopic examination of the urine were negative. The blood glucose level was 1,200 mg.%. The serum amylase level was 700 units per 100 cc. (corrected for the high glucose level in the blood). The cerebrospinal fluid was normal. The blood urea nitrogen level was 100.8 mg.%.

On the second hospital day the patient developed shock, her temperature rose to 104 F (40 C), and she became comatose. A constant intravenous infusion of arterenol was required to sustain her blood pressure level. However, with the help of intravenous administration of fluids, maintenance of constant gastric suction, and administration of anticholinergic drugs and insulin, she slowly regained consciousness, her abdominal pain disappeared, and her blood urea nitrogen and fasting blood sugar returned to normal levels. The serum amylase level was 280 units per 100 cc. on the 5th hospital day, 365 units on the 8th day, and 50 units on the 12th day. Roentgenograms of the gallbladder and upper part of the gastrointestinal tract taken when the patient became ambulatory were normal. An electrocardiogram revealed a pattern of left ventricular hypertrophy. On the 48th hospital day the patient was transferred to a nursing home for continued supportive care.

She was seen again on Jan. 12, 1959, in the outpatient department of the hospital. Her blood pressure was 200 mm. Hg systolic and 130 mm. Hg diastolic. She felt well and had had no further abdominal pain. Urinalysis revealed no sugar or acetone. The fasting blood sugar level was normal, and the administration of insulin was no longer necessary.

Case 3.—The patient was a 71-year-old widow who had been chronically ill with rheumatic heart disease, mitral insufficiency, and chronic congestive heart failure for about three years. She had been on a low-salt diet and therapy with digitoxin and mercurial diuretics until December, 1958, when the administration of chlorothiazide, 0.5 Gm. daily, was substituted for the mercurial diuretics.

On March 30, 1959, the patient suddenly began to have severe generalized abdominal pain with nausea and vomiting. The pain was steady and only temporarily relieved by administration of meperidine hydrochloride. The patient was, therefore, admitted to the hospital. She had no family history of pancreatitis. She never had consumed alcoholic beverages. Physical examination revealed an acutely ill, nauseated, dyspneic female. The blood pressure was 170 mm. Hg systolic and 100 mm. Hg diastolic. The pulse rate was 80 beats per minute. The respirations were rapid and shallow. Her temperature was 97 F (36.1 C). Examination of the ocular fundi revealed arteriolar sclerosis, grade 2 (according to the classification of Keith, Wagener, and Barker). The heart was enlarged to the left anterior axillary line, with a diffuse, heaving, apical impulse and a grade 4 systolic apical murmur. Auscultation of the lungs revealed a few medium moist rales in both bases. Abdominal examination revealed generalized tenderness, which was most marked in the upper part of the abdomen, accompanied by involuntary muscle spasm and rebound pain. There was moderate gaseous distention, and peristaltic activity was markedly decreased. The peripheral pulses were full and equal, and there was no pitting edema of the ankles or legs. Results of rectal examination were negative. The patient was somewhat confused and irrational. Her lips were cyanotic. The concentration of hemoglobin was 11.9 Gm. per 100 cc. of blood. The leukocyte count was 16,150 per cubic millimeter of blood, with 94% segmented neutrophils. Urinalysis revealed albuminuria (1+) and 2 to 3 white blood cells per high-power field. The serum amylase level was 925 units per 100 cc. A plain roentgenogram of the abdomen revealed a calcified, tortuous aorta but no other abnormality. The roentgenogram of the chest revealed the lung fields to be clear but the heart markedly enlarged. The blood calcium level was 7.5 mg.%.

The diagnosis of acute pancreatitis was made. The patient's severe abdominal pain persisted, and she was treated with constant gastric suction and administration of anticholinergic drugs, sedatives, mercurial diuretics, digitoxin (Crystodigin), penicillin, and streptomycin. Because of cyanosis and respiratory distress, administration of oxygen was necessary during the first week of hospitalization. Over a period of nine days the patient's condition slowly improved. Her abdominal pain disappeared, she became mentally clear and rational, the cyanosis disappeared, the dyspnea markedly improved, and she was able to take a soft diet without difficulty. Roentgenograms of the gallbladder and upper part of the gastrointestinal tract on the 14th hospital day were normal. The serum amylase level just prior to the patient's dismissal was 70 units per 100 cc.

Comment

In the majority of cases of acute pancreatitis, either alcoholism or associated disease of the biliary tract is present. In a statistical review, Paxton and Payne[5] found either associated cholecystic disease or alcoholism in 62% of 307 established cases of acute pancreatitis. In the remaining 38% of the cases the etiology of the disease was unknown. To our knowledge, no drug or chemical other than alcohol has been incriminated as an etiological factor in pancreatitis. However, our observation during the past year of the development of severe acute pancreatitis in three patients who were receiving chlorothiazide leads us to suspect that this may be more than a coincidence. None of these three patients was an alcoholic or had associated biliary tract disease. All were middle-aged or elderly females. All had received chlorothiazide daily for several months. None had developed any untoward digestive symptoms or evidence of gastric irritation. None had a family history of pancreatitis. All had serious vascular disease. The pancreatitis was fatal in one case. The other two patients recovered, after prolonged hospitalization.

Summary and Conclusions

During the past year we have observed the development of acute pancreatitis in three patients (all middle-aged or elderly females) who had been receiving chlorothiazide daily for several months and who did not have associated biliary tract disease, alcoholism, or any other of the conditions usually considered important in the etiology of pancreatitis. By reporting these cases, we hope to draw the attention of others to the possible development of pancreatitis in patients who receive chlorothiazide.

Addendum

Since the submission of this manuscript, we have observed a fourth example of pancreatitis associated with the administration of chlorothiazide. The patient is an 84-year-old man with arteriosclerotic heart disease and chronic congestive heart failure, who had taken 1 Gm. of chlorothiazide once or twice a week for 15 months. He is now in the hospital with typical acute pancreatitis. The initial serum amylase level was 890 units per 100 cc. To date he is not well enough for cholecystography, but he gives no history suggestive of gallbladder disease. He has never used alcoholic beverages.

CLINICAL THERAPEUTIC EVALUATION OF HYDROCHLOROTHIAZIDE (HYDRODIURIL)

George Schwartz, M.D., George H. Steehel, M.D., Stanley I. Fishman, M.D.
and
Arthur Fankhauser, M.D., Brooklyn, N. Y.

In most patients treated earlier with chlorothiazide, maintenance of the previous status was obtained with a dose of hydrochlorothiazide one-tenth that of chlorothiazide. An important advantage appears to be absence of complaints of weakness during early weeks of treatment. Intravenous administration of hydrochlorothiazide is convenient and effective therapy. In oral therapy, daily administration is preferred because a more constant level of "compensation" is desirable. Hypertensive patients without clinical congestive failure showed improvement both symptomatically and by fall in blood pressure.

The advent of chlorothiazide initiated a new era in diuretic therapy. Since its evaluation by an unusually large number of investigators, this remarkable compound has become a valuable therapeutic tool for countless practicing physicians. Orally given chlorothiazide is as powerful a diuretic as parenterally given mercury and does not itself become ineffective with continued use.[1] It resembles structurally the carbonic anhydrase inhibitors and pharmacodynamically the organomercurial diuretic drugs. The primary effect appears to be inhibition of renal tubular reabsorption of sodium and chloride, resulting in a secondary increase in water excretion. There appears to be some carbonic anhydrase inhibitory effect on the renal tubules, particularly with the use of larger doses.[2]

Further exploration of the benzothiadiazine chemistry by Novello and Sprague resulted in the synthesis of hydrochlorothiazide (Hydrodiuril), the dihydro derivative of chlorothiazide, having no double bond in the heterocyclic ring. Renal clearance studies show that hydrochlorothiazide is cleared by the kidney at a rate greatly in excess of glomerular filtration, attributable to secretion by the epithelial cells of the renal tubule. Preclinical evaluation with various doses demonstrated that the increase in cation excretion that resulted from increasing the dose of hydrochlorothiazide was completely covered by an equal increase in chloride excretion. In the case of chlorothiazide, however, a portion of the cation was covered by an increased bicarbonate excretion (increase in urine pH). The kaliuretic effect in these experiments was the same for both compounds. These findings may be of significance in assessing the clinical results with these compounds.

Materials and Methods

Case Material.—One hundred eighteen patients were selected for treatment with hydrochlorothiazide, of whom 106 were outpatients. Duration of therapy was approximately four months (18 weeks for 69 patients and 17 weeks for 37 patients). Studies with chlorothiazide had been done previously in the majority of these patients; they were classed with those having edema of marked severity, since poor response to organomercurial therapy was seen prior to the administration of chlorothiazide.[3]

Group A included 83 patients previously treated with chlorothiazide, of whom 9 had Laennec's cirrhosis, 32 hypertensive heart disease, and 42 arteriosclerotic heart disease. In regard to severity of heart disease, 26 patients were in functional class 4 and 48 in class 3 (New York Heart Association classification). Group B included 35 patients not previously treated with chlorothiazide. Twenty-three patients in this group received hydrochlorothiazide orally and 12 received this agent intravenously (LyoHydrodiuril). Those receiving the drug orally included six patients with hypertension (without clinical evidence of congestive failure), one with Laennec's cirrhosis, seven with hypertensive heart disease, and nine with arteriosclerotic heart disease. Those receiving the drug intravenously included two patients with Laennec's cirrhosis, four with hypertensive heart disease, and six with arteriosclerotic heart disease. There were 5 class 4 and 11 class 3 patients among those with cardiac disease who received the drug orally and 3 class 4 and 7 class 3 patients who received it intravenously.

Poor response to organomercurial therapy was a requirement for those patients in group A prior to their original treatment with chlorothiazide; this requirement was not strictly used in the present study for patients in group B, for the practical reason that patients who show poor response to organomercurials and in whom chlorothiazide has not been tried are difficult to find. It is possible, therefore, that the group B patients may not be

considered as severely ill as were those in group A prior to chlorothiazide therapy; nevertheless, the patients with cardiac failure certainly were among the most edematous of those seen at Kings County Hospital Center.

Thirteen patients with hypertension, who had not previously received chlorothiazide, were given hydrochlorothiazide orally; six of these patients had no clinical evidence of salt and water retention. They are included in this study with the realization that patients with "essential" hypertension may have a slightly elevated serum sodium concentration, expanded total body sodium content, and increased amounts of sodium and water in arterial walls.[4]

Method.—No change in routine was made for the patients in group A (previously treated with chlorothiazide), with the exception of simply substituting hydrochlorothiazide for chlorothiazide. In group B, all diuretic therapy was discontinued, and hydrochlorothiazide was added to the therapeutic regimen. Other than these changes, all measures remained the same and no withdrawal period was used. The patients in this study seldom have been given a low-sodium diet, and they were asked to continue their previous habits—little urging was required. Patients were examined at weekly intervals, and appropriate laboratory studies were done as indicated.

Dosage.—Hydrochlorothiazide was supplied in 25-mg. and 50-mg. compressed tablets and in ampuls containing 50 mg. as powder for reconstitution with distilled water for intravenous use. Patients who had previously received chlorothiazide were given hydrochlorothiazide at one-tenth the dose of chlorothiazide. In group B, those with class 3 cardiac disease were given 50 mg. of hydrochlorothiazide twice daily, as were those with hypertension without overt evidence of congestive failure. Patients with class 4 cardiac disease and those with cirrhosis were given 100 mg. of hydrochlorothiazide twice daily. Patients who received the drug intravenously were given 50 mg. of hydrochlorothiazide in 5 ml. of distilled water once a day; 8 of these 12 patients received two to four such treatments at two-day intervals.

In general, for patients receiving oral therapy, daily administration is preferred in the belief that a more constant level of "compensation" is desirable; this is thought to be one of the main advantages of benzothiadiazine therapy over that with organomercurial agents, which, of necessity, are rarely given daily. To give the benzothiadiazines on an intermittent schedule would eliminate this advantage. From a practical standpoint, the patient is less likely to make mistakes if the habit of administration is a daily one. One dose daily is, of course, ideal if this is sufficient to maintain the desired status; if more than one dose is required, administration at breakfast and at the evening meal is advised, since this approximates 12-hour intervals and eliminates the need for working patients carrying a dose of the drug for midday administration. On this regimen, some patients complain of the necessity of arising at night to urinate, and in these instances administration at breakfast and at lunch is then substituted.

Results

In the majority of the 83 patients previously treated with chlorothiazide, maintenance of the previous status was obtained with a dose of hydrochlorothiazide one-tenth that of chlorothiazide. In approximately one-fourth of these patients, the 10:1 dosage relationship did not hold true, and further adjustment was necessary, with dosage relationships usually resulting in a final ratio of 10:1.5 or 10:2. This minor difficulty offers only temporary inconvenience in changing from chlorothiazide to hydrochlorothiazide therapy. Among the patients who had not previously received chlorothiazide, the original estimated dose requirement was found to be correct for most patients, i. e., 50 mg. of hydrochlorothiazide twice daily for patients with class 3 heart disease and for those with hypertension without overt congestive failure and 100 mg. twice daily for those with class 4 heart disease and for those with cirrhosis. Individual variations were, of course, encountered, and the over-all dosage range is from 25 mg. to 300 mg. daily. One exceptional patient received 450 mg. of hydrochlorothiazide daily and 2 ml. of meralluride three times a week; this patient was formerly receiving 4.5 Gm. of chlorothiazide daily plus the same dose of meralluride. The effective period of action appears to be somewhat shorter for hydrochlorothiazide than for chlorothiazide, and administration three times daily was instituted for approximately one-fifth of patients.

Maintenance of edema-free, compensated status in 83 patients previously treated with chlorothiazide was accomplished with the doses noted above. In 17 patients who had never received chlorothiazide, hydrochlorothiazide produced the same dramatic improvement now familiar with chlorothiazide. Weight and water loss, improvement in the general sense of well-being, diminution or disappearance of edema, and improvement in symptoms were again noted.

No patient in the present study can be classed as showing a therapeutic failure. Only one patient received meralluride; in all other instances control of congestive failure was achieved with digitalis and hydrochlorothiazide, without other adjunctive therapy.

Hypertension.—Patients who had previously received chlorothiazide demonstrated no further change in blood pressure. Patients being treated with antihypertensive agents (usually reserpine) other than chlorothiazide demonstrated a further fall in blood pressure in the order of 20 to 30 mm. Hg systolic and 0-10 mm. Hg diastolic when hydrochlorothiazide was added.

Of six patients with essential hypertension without clinical evidence of congestive heart failure who had never received chlorothiazide and who received no therapy other than hydrochlorothiazide, all demonstrated an improvement in blood pressure and in symptomatology. The range of fall in blood pressure was 50-80 mm. Hg systolic and 10-20 mm. Hg diastolic, usually occurring within the first week of therapy. Postural hypotension was not troublesome symptomatically, though it was occasionally noted on examination. Five of these six patients also had a loss of weight of 3 to 5 lb. (1.3 to 2.3 kg.), which may be considered as water loss. It seems reasonable to suppose that at least a part of the antihypertensive action of hydrochlorothiazide is referrable to improvement of abnormal salt and water metabolism in hypertensive patients presumably free of congestive failure.

Side-effects.—Three patients discontinued hydrochlorothiazide treatment after two to three weeks because of epigastric distress. Two patients developed elevated serum uric acid levels, and one complained of aching knee joints. It has been suggested that these patients have "latent gout" and that the high uric acid levels are due to concentration effects by hydrochlorothiazide in cases of previous decompensation; a more tenable explanation postulates a direct effect on renal tubular metabolism.

No adverse effect on liver function findings or blood cellular constituents was noted. There was no significant change in blood urea nitrogen levels. One patient with Laennec's cirrhosis experienced generalized pruritus and mild diarrhea for two days after the administration of 50 mg. of hydrochlorothiazide intravenously.

Blood Electrolytes.—Changes in serum sodium concentration have been small in degree, inconstantly found, and within normal ranges in all instances. A small drop in serum chloride concentration was common and tended toward reversal by the second week of therapy. There was no significant change in carbon dioxide content.

With chlorothiazide therapy, a significant number of patients complain of weakness during the first one to two weeks of treatment; this symptom disappears usually spontaneously and sometimes with the addition of potassium, either in diet or by tablet. Some instances of proved hypokalemia have been demonstrated. In the present study with hydrochlorothiazide, no evidence of hypokalemia has been demonstrated by serum or electrocardiographic study. No patient was given supplementary potassium chloride or dietary potassium. More significantly, no patient complained of weakness at any time during the study. This finding appears to be the most distinct advantage of hydrochlorothiazide over chlorothiazide.

The lack of weakness with hydrochlorothiazide is certainly a welcome finding, but the explanation remains obscure. Because of the difficulty in proving hypokalemia, it has been supposed that the weakness seen with chlorothiazide therapy was related to low potassium content not demonstrated chemically or electrocardiographically. In a recent series of cases of pregnant women with edema treated with chlorothiazide, approximately two-thirds complained of weakness within the first 48 hours of therapy.[5] It is easy to imagine that pregnancy, with increased amounts of adrenal corticosteroids, might make these patients particularly prone to hypokalemia, but, if this is true, the fact that these women did not respond to supplementary administration of potassium is surprising. Moreover, despite the difficulty in demonstrating low potassium content, a larger percentage of those patients with weakness would be expected to show either serum or electrocardiographic change than has actually been the case. Finally, as has been noted, the kaliuretic effect in animal experiments was the same for both chlorothiazide and hydrochlorothiazide, casting further doubt on the role of potassium in the production of weakness with chlorothiazide or the lack of weakness with hydrochlorothiazide. Whatever the cause, hydrochlorothiazide appears to hold an advantage in this respect.

Intravenous Administration.—Twelve patients received hydrochlorothiazide intravenously, with 50 mg. in 5 ml. of distilled water injected once a day and given again two to four times at two-day intervals in 8 of these 12 patients. Loss of weight 24 hours after administration ranged from 2 to 8 lb. (0.9 to 3.6 kg.), and a reduction of 1+ to 2+ in peripheral edema was noted. Administration by this method is fairly convenient and appears efficacious when parenteral administration is required.

Summary

In 83 patients, hydrochlorothiazide (Hydrodiuril) was substituted for chlorothiazide with relative ease and the edema-free, "compensated" status was maintained with dosages approximately one-tenth those of the latter compound. In 17 patients who had not received chlorothiazide, hydrochlorothiazide produced the same beneficial results as would be expected from chlorothiazide. Hypertensive patients without clinical congestive failure showed improvement both symptomatically and by fall in blood pressure. In patients requiring parenteral administration, intravenous administration of hydrochlorothiazide is convenient and effective therapy. The most important advantage appears to be the lack of weakness in patients receiving hydrochlorothiazide.

20 Eighth Ave. (17) (*Dr. Fishman*).

The hydrochlorothiazide used in this study was supplied as Hydrodiuril by Merck Sharp & Dohme, Inc., division of Merck & Company, Inc., Philadelphia.

HEMORRHAGE FROM MULTIPLE SITES ASSOCIATED WITH CHLORPROMAZINE-INDUCED JAUNDICE

Martin Floch, M.D.
and
Sidney Leibowitz, M.D., New York

Hemorrhage occurs rarely during medication with chlorpromazine, and then usually as purpura, without jaundice. Jaundice occurs more commonly; its estimated incidence is 1 to 2%. However, hemorrhage and jaundice can appear together during administration of the drug. A 66-year-old woman had been taking 75 mg. of the drug for 17 days when the yellow color of her skin was first noticed. Three days later she bled spontaneously from the vagina, rectum, and urinary tract, and ecchymotic areas appeared in the skin of the knees. Hypoprothrombinemia due to a toxic action of the drug was considered the cause of the hemorrhage and was corrected promptly by vitamin K_1 therapy; the jaundice secondary to the chlorpromazine-induced hepatitis persisted into the fourth week.

Chlorpromazine, first synthesized in 1951 in France, where it was introduced as an adjunct to anesthesia, has been available in the United States since May, 1954. It has been used for many purposes but mainly to allay neuropsychiatric disorders, to control nausea and vomiting of varied causes, to overcome hiccups, and to diminish intractable pain.

Its side-effects include excessive dryness of the mouth, drowsiness, tachycardia, depression, nasal stuffiness, and a Parkinsonian type of gait and tremor. Distinct from these side-effects are toxic effects, of which the main ones are fever, maculopapular skin eruption, agranulocytosis, and, lastly and probably most important, jaundice.

The incidence of jaundice is difficult to assess accurately. It is approximated as between 1 and 2% when large separately reported [1] series of cases are added together. After five years of its use in the United States, its manufacturer estimated that more than 13 million people had received the drug. Its widespread use continues and the literature is now studded with reports of resulting jaundice and even of cases of liver involvement without clinically detectable jaundice.[2]

With but one exception thus far, no major or minor bleeding has been reported in association with jaundice after use of the drug. The exception is the third of the three cases reported in 1955 by van Ommen and Brown.[3] This patient bled, presumably from a duodenal ulcer. As in most reported cases the prothrombin time was normal.

Among the reports of cases in which there was no jaundice associated with chlorpromazine administration, there are four references to hemorrhagic manifestations. Mullins and associates [4] mention purpuric manifestations among the skin eruptions observed in a series of 85 patients, specifically citing the observation of petechial eruptions in two patients. Platelet counts were normal. Childers [5] reported the development of nonthrombocytopenic purpura in

---

From the Medical Service, Beth Israel Hospital.

two cases. Prothrombin activity was not significantly prolonged (recorded as 78% of normal in one case and 75% in the other). Marley[6] referred to nonthrombocytopenic purpura in one patient who manifested no other bleeding abnormality. Giacobini and Lassenius[7] reported on 147 patients, observing epistaxis in 7, gingival and uterine bleeding in 2, and conjunctival hemorrhage in 2.

Almost without exception, the prothrombin time has been found to be normal or near normal in the patients with hepatitis induced by chlorpromazine.[8] The sole possible exceptions known to us are reports of two jaundiced male patients in whom the respective prothrombin determinations were recorded as 45% and 62% of normal.[9] In neither instance was bleeding described. (Bleeding is ordinarily not encountered even at these levels of prothrombin activity, which generally correspond to times of 16 to 18 seconds.)

Because of the rarity of the occurrence of any bleeding tendency in conjunction with chlorpromazine therapy and its even greater rarity in the presence of jaundice so induced, the following case is reported as an instance of bleeding from numerous sites (skin, rectum, vagina, and urinary tract) in association with jaundice induced by chlorpromazine ingestion. The rectal hemorrhage was massive; the other bleeding was relatively subdued. No cause for the bleeding was elicited other than that associated with the drug-induced jaundice.

Report of a Case

A 66-year-old woman was admitted to Beth Israel Hospital on April 2, 1958, with a chief complaint of yellow color of the skin of three days' duration. The patient had presented herself to the outpatient department on Feb. 5, 1958, with a three-week history of nausea, constipation, and mild abdominal pain. She subsequently attended both the mental health and gastrointestinal clinics. Sigmoidoscopy and roentgenographic examination of the colon showed normal results. Seven weeks prior to admission to the hospital she had been placed on therapy with reserpine and meprobamate with little relief of her symptoms. Three weeks prior to admission the medication was changed to 25 mg. of chlorpromazine, three times daily, by mouth. Three days prior to admission the patient noted the onset of the yellow color of her skin. When this persisted she consulted a local physician who referred her to the hospital.

The patient had not observed the color of her stools but had noted increasingly dark urine with the onset of jaundice. Her appetite was good. There was no history of pruritus, skin eruption, fever, melena, or hematuria. Three days prior to admission she had removed a pessary, worn for uterine prolapse and cystocele. After its removal, she had noted slight bleeding similar to that which had occurred on previous occasions.

The patient had a history of mild hypertension for six years, treated at times with reserpine. A thyroidectomy had been performed 25 years before for hyperthyroidism. The family history and review of systems were essentially noncontributory.

Physical examination revealed a well-developed and well-nourished female in no acute distress but grossly icteric. She was lucid and cooperative. The pulse rate was 80 per minute, blood pressure 150/80 mm. Hg, and temperature 100 F (37.8 C). Marked icterus of both scleras and fundi was observed. No lymph nodes were palpable. The lungs were clear to auscultation and percussion. The heart revealed a grade 2 apical systolic murmur. The abdomen was soft. A smooth nontender liver edge was palpable 3 cm. below the right costal margin. Trophic skin changes and varicosities were evident on the lower extremities. Irregular and macular ecchymotic areas 2 to 3 cm. in size were noted over both knees. Rectal examination showed negative findings. Digital pelvic examination revealed only prolapse and cystocele.

On admission of the patient the hemoglobin level was 13.2 Gm.%, with a hematocrit value of 37%. The white blood cell count was 6,800 per cubic millimeter, with a normal differential count. A catheterized urine specimen revealed a specific gravity of 1.012, with 10 to 15 red blood cells per high-power field and presence of bile (3+) with no increase in urobilinogen.

Several hours after admission the patient passed a few large blood clots from the vagina. Immediate reexamination with speculum by the consultant gynecologist revealed several small bleeding erosions of the vagina at the site of the previously worn pessary. The vagina was packed and the patient appeared comfortable. Twelve hours later (about 2 a. m., April 3, 1958) the patient suddenly had two grossly bloody bowel movements consisting of approximately 700 cc. of dark red blood mixed with clots. Examination at this time demonstrated a blood pressure of 80/60 mm. Hg and a pulse rate of 100 per minute. An infusion of 5% dextrose in water was begun. Before any blood replacement was started the pressure rose to 130/70 mm. Hg. Because of the multiple bleeding sites (skin, vaginal, urinary, and rectal) the possibility of prothrombin deficiency was considered. An emergency blood specimen was taken at this hour for prothrombin time determination to be done later that morning. Fifty milligrams of vitamin K_1 oxide was then administered intravenously. (Due to technical reasons this blood specimen drawn on emergency basis for prothrombin time determination was not suitable for evaluation in the morning.) Proctoscopic examination revealed an ulcerated bleeding hemorrhoid, the area around which was packed with absorbable gelatin sponge. No major recurrence of bleeding from any site was observed thereafter, but minor bleeding did continue for several days as evidenced by microscopic hematuria, rectal ooze, and positive tourniquet test.

The hemoglobin level was 9.2 Gm.% on the morning of April 3, 1958, and the hematocrit value was 24%. The prothrombin time (Quick) on a blood specimen drawn at 9 a. m., April 3, 1958, was 14.1 seconds, with a control of 12.8 seconds. The white blood cell count was 7,450 per cubic millimeter, with a normal differential count. The bleeding time was 3 minutes, coagulation time 9 minutes (Lee-White), and clot retraction time one hour. The platelet count was within normal limits. The fasting blood sugar level was 183 mg.%. The serum bilirubin value was 11.9 mg.%, the thymol turbidity 2.1 units, and the cephalin flocculation a trace at 48 hours. The alkaline phosphatase level was 10.7 Bodansky units, the total cholesterol level 290 mg.% and the cholesterol esters 150 mg.%. The serum glutamic oxalacetic transaminase (SGO-T) value was 73 units.

A chest roentgenogram showed a mild scoliosis with slight enlargement of the heart, pleural adhesions, and apical fibrotic changes. Roentgenographic examination of the esophagus, stomach, and small and large intestine was within normal limits. The gallbladder was well visualized with excellent contractility after a fatty meal. An electrocardiogram showed evidence of a left ventricular strain and hypertrophy. A liver biopsy was performed on the 37th hospital day, but insufficient tissue was obtained for diagnosis. Oral glucose tolerance tests performed on the 7th and 39th hospital days demonstrated a distinct diabetic curve.

Except for a low-grade fever, with temperatures to 100.5 F (38 C), attributed to a chronic cystitis secondary to her cystocele, the patient made an uneventful recovery. On the third hospital day the urine was free of red blood cells, and by the end of the first week all vaginal and rectal bleeding had ceased. No blood replacement was necessary. The patient was prescribed a full diet of 325 Gm. of carbohydrate, 120 Gm. of fat, and 150 Gm. of protein daily, which she consumed voraciously almost from the beginning of her hospital period. In addition she was given therapeutic vitamins daily and a tablet of ferroglycine sulfate complex three times daily.

At the end of the patient's first week in the hospital, the hematocrit value had slowly risen to 30%. The serum bilirubin level reached a maximum of 19.9 mg.%, with 8.2% direct fraction. The cholesterol (total) level rose to 410 mg.%; the alkaline phosphatase level was 19.4 Bodansky units. The SGO-T value decreased to 50 units, and both cephalin flocculation and thymol turbidity remained normal.

By the second week all evidence of ecchymosis had disappeared. The patient was permitted out of bed on the 21st day, and by the 28th day clinical evidence of jaundice had disappeared. Proctoscopy just prior to discharge revealed complete healing of the eroded hemorrhoid. On the 42nd day after admission the patient was discharged to the clinic, where she was followed for three months with no recurrence of jaundice or evidence of further bleeding.

Comment

There can be little doubt concerning the basic diagnosis of chlorpromazine-induced jaundice. The clinical appearance of jaundice on or about the 17th day of drug ingestion is typical. The chemical laboratory data are equally typical, showing hypercholesteremia and hyperphosphatemia (alkaline) with normal flocculation tests and relatively little rise in the SGO-T level. The degree of hyperbilirubinemia (up to 19.9 mg.%) is well within the zone attained when jaundice is associated with this drug.

The hyperglycemia appeared to be an independent finding related to a coincidental occurrence of diabetes mellitus. The peripheral blood findings (normal white blood cell count with minimal polynucleosis) is quite compatible with this diagnosis. The frequent finding of eosinophilia was not fulfilled in this instance. Biopsy of the liver, not attempted until the 37th day in the hospital, unfortunately was of no practical assistance because of the insufficient tissue obtained. It is entirely possible, of course, that by this time the histological picture might no longer have been diagnostic or even abnormal.

A striking observation by the medical attendants in this case was the appetite manifested by this patient almost from the first days in the hospital, when the bleeding had quieted down and feeding by mouth was resumed. It was a situation which evoked considerable comment by physicians and nurses: she fairly leaped at her tray and devoured all food in sight rapidly, uninterruptedly, and completely. This could hardly be explained by her history of thyroid disease, and she was found to be euthyroid in the current period of hospitalization. We had not observed this in previous cases of chlorpromazine-induced jaundice, nor does the literature remark on it.

Nothing resembling this excessive hunger and appetite is ordinarily observed in hepatitis of viral origin. Occasionally in the recovery stage of acute viral hepatitis, excessive food intake becomes a problem in the future management of the patient because of the tendency to rapid and extreme weight gain[10] but is ordinarily not seen from the peak of the illness. However, in our experience with chlorpromazine-induced jaundice, it is highly characteristic to observe relative well-being almost from the onset of the illness. Disproportion exists between the depth of the jaundice and the relative lack of discomfort and complaint by the patient, with the possible exception of pruritus early in the illness.

Hemorrhage is an exceedingly rare manifestation of chlorpromazine-induced hepatitis with jaundice, as has already been pointed out, and is only slightly less infrequent in the patient receiving this drug who does not develop jaundice. In our jaundiced patient the bleeding appeared from four sites, being of major importance from the rectal mucosa and less prominent in the vagina, the urinary tract, and skin over the knees. The cause is not absolutely clear, but in the absence of a more satisfactory alternative explanation a likely one is hypoprothrombinemia. Absolute proof of the existence or lack of existence of such hypoprothrombinemia at the onset of hemorrhage is lacking because of the unfortunate technical deficiency in handling the blood sample drawn soon after the occurrence of the rectal hemorrhage and prior to the administration of the vitamin K_1. About seven hours had elapsed by the time another sample of plasma had been obtained for prothrombin time determination. The reading was then 14.1 seconds with a control of 12.8 seconds. Twenty-four hours later it was 13 seconds, equal to the control.

When vitamin K_1 is administered intravenously, bleeding is usually controlled within 3 to 6 hours, and a normal prothrombin time (if previously markedly elevated, enough to initiate hemorrhage) may often be obtained within 12 to 14 hours. It cannot be concluded beyond question that the assumed plasma prothrombin diminution was thus restored toward normal by the vitamin K_1. Nonetheless, it is tempting to make this assumption because of the later (secondary?) rise in prothrombin time to 16 seconds, when next tested a week later on the 11th hospital day. However, it is recognized that seven hours is ordinarily too brief a period in which to anticipate a considerable reduction in the prothrombin time by means of vitamin K therapy, although it may occur.

The mechanism whereby such reduction of prothrombin time might have been accomplished by parenterally given vitamin K_1 is not fully clear. Generally it is felt that the hepatic involvement due to chlorpromazine is a result of a sensitivity reaction with consequent interference with the normal flow of bile from liver cell to bile radicle. In viral hepatitis, toxic hepatitis, and other diseases in which the parenchyma of the liver is diffusely injured or destroyed, the reduced plasma prothrombin content responds little or not at all to vitamin K. On the other hand, in case of biliary obstruction or of bishydroxycoumarin-induced reduction of plasma prothrombin content, the effect of parenterally given vitamin K is to correct the prothrombin deficiency.

Thus, if a reduced prothrombin content in the blood was counteracted or corrected by vitamin K_1 in our case, it is fair to conclude that the inflammatory reaction in the liver due to chlorpromazine must differ from that occurring in viral hepatitis. This conclusion is supported by our knowledge of the difference in the histology of the liver in these two disease states.

It should be stressed that in diseases of the liver there are factors in blood coagulation other than prothrombin, such as proconvertin (factor VII) and accelerator globulin (factor V or proaccelerin). Our measurement of prothrombin time by the Quick method does not delineate the respective roles and presence of these additional factors.[11] All these factors affect the prothrombin time, and when we demonstrate a deficiency in prothrombin we cannot be certain which is at play.

In the face of the jaundice, in the absence of recognition of any other factor promoting bleeding, such as platelet deficiency, and in view of the rapid cessation of bleeding on administration of vitamin K_1, we are inclined to believe that hypoprothrombinemia was the cause. It has already been pointed out that this is an extremely rare finding in the experience of those who have measured prothrombin activity in chlorpromazine-induced hepatitis. The few instances of bleeding associated with the use of chlorpromazine have been mild and observed almost exclusively without the development of jaundice. The rarity of this occurrence is the reason for recording this experience.

Summary

A 66-year-old diabetic woman bled from multiple sites (rectum, vagina, urinary tract, and skin) in association with jaundice induced by chlorpromazine, administered for 17 days. The likely explanation for the hemorrhage is hypoprothrombinemia, although there is a possibility of defects in other coagulation factors. Note is taken that depressed prothrombin activity after chlorpromazine ingestion is uncommon. Hemorrhagic manifestations in association with the administration of chlorpromazine are rare. Particularly is this infrequent in reported cases of jaundice. Minor bleeding has been noted in the absence of jaundice, usually in the form of purpura. A striking clinical observation in this patient was the voracious appetite she manifested from the height of her illness.

OTOTOXICITY OF KANAMYCIN

REPORT OF THREE CASES

G. Garrido Lecca, M.D., Jorge Terry, M.D., Luis Maggiolo, M.D.
and
Alejandro Morales, M.D., Lima, Peru

Severe and apparently permanent loss of hearing was observed in three patients who received kanamycin in the treatment of serious infections. One man, aged 46 years, received 40 Gm. in the course of 16 days; another, aged 62, received 14 Gm. in the course of 7 days. In these cases tinnitus preceded the impairment of hearing. A woman aged 55 received 14 Gm. in two courses separated by an interval of five days. In her case there was no warning tinnitus. In all cases the deafness progressed after administration of the kanamycin was stopped; loss of hearing has been practically complete, and no improvement has been found at later examinations.

The new antibiotic kanamycin, discovered by Umezawa in 1957, is still under clinical observation, and we believe that all serious toxic effects should be reported in order to establish its uses and limitations. This is necessary in the study of any new antibiotic, inasmuch as these are frequently coming on the market.

Report of Cases

Case 1.—A 46-year-old man was admitted to the hospital because of hematemesis of 24 hours' duration. About 15 years previously the patient had had paratyphoid. Two years ago he was operated on because of a hernia of the nucleus pulposus, with good results.

Present Illness.—The patient stated that about five years previously he began to notice epigastric discomfort two to three hours after meals; this was relieved by taking food or antacids. The pain became worse and was so severe that the patient was awakened at night. His physician treated him for peptic ulcer, in spite of negative findings of roentgenographic study. He improved with this medication, although he said that he had periods of pain in the same area which were rapidly relieved by taking antacids. After the treatment he had another series of roentgenographic studies of the stomach and again the findings were normal.

Two years before the present admission, when he had been in Johns Hopkins Hospital for an operation on the spinal column, the patient had another roentgenographic study and for the first time was told that he had a healed duodenal ulcer. The roentgenogram showed a deformity of the duodenum.

From the departments of medicine, otolaryngology, and urology, British American Hospital.

He felt all right until three months before admission, when he again had epigastric pain, relieved by taking food or antacids. Twenty-four hours before admission the patient felt weak and noticed black stools for the first time. Four hours before admission he felt extremely weak and dizzy, vomited blood, and became very pale. A physician was called and found him in mild shock; he was therefore referred to the British American Hospital for further treatment.

Physical Examination.—On admission the patient was pale, perspiring profusely, and somewhat nervous. His blood pressure was 80/40 mm. Hg, pulse 120, and respirations 24 per minute. The physical examination was noncontributory except for signs of mild shock. He immediately received a blood transfusion. In two and one-half days he received a total of 2,000 cc. of blood, after which the hematocrit fluctuated between 25 and 26%, and the hemoglobin concentration between 8.26 and 8.58 Gm.%. More transfusions were given until the hemoglobin value became 11.74 Gm.% and the hematocrit 38%, so that he could be operated on on his third hospital day.

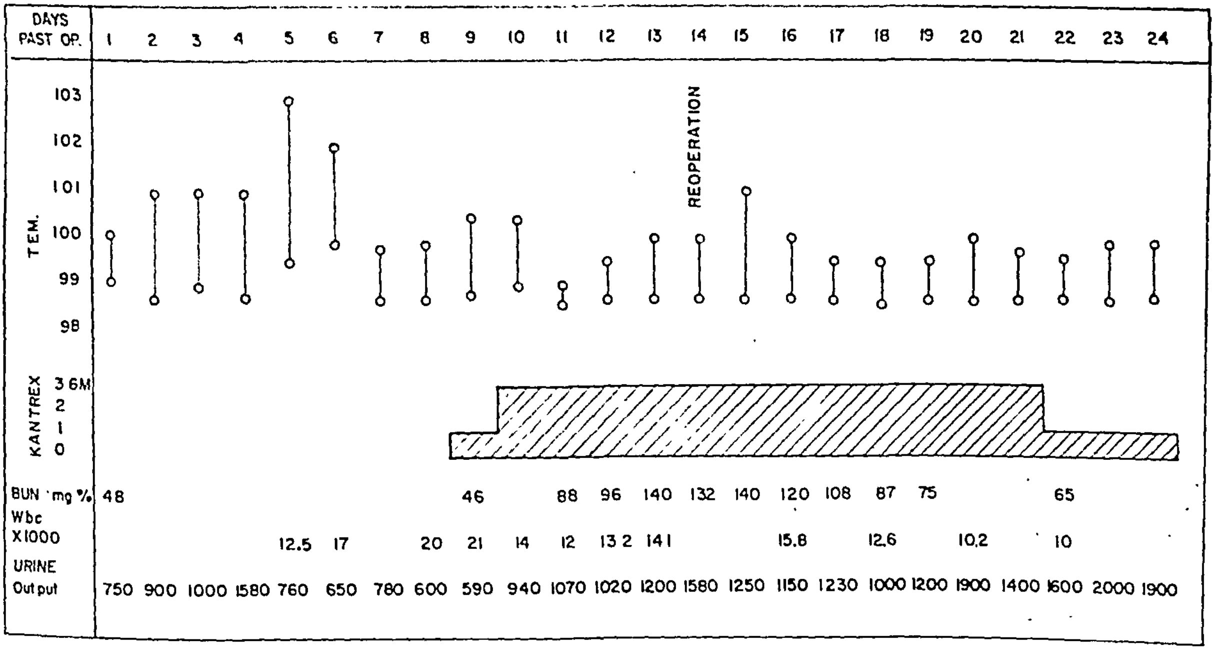

Fig. 1 (case 1).—Chart showing temperature, urinary output, blood urea nitrogen level, and white blood cell count in relation to administration of kanamycin (Kantrex).

An extensive gastrectomy (Hofmeister-Finsterer) was performed. By the time the patient returned to his room the hemoglobin level was 11 Gm.% with a hematocrit of 39%. The patient then received 1 Gm. of oxytetracycline intravenously for three successive days, during which period his temperature fluctuated between 99 and 100 F (37.2 and 37.8 C). It became normal on his fourth postoperative day, and the antibiotic therapy was discontinued. He was doing well except for the pulse, which remained between 100 and 110 per minute. The laboratory studies before the operation showed normal coagulation, bleeding, and prothrombin times. Blood urea level was 48 mg.%, the urine was normal, and the serologic examinations gave negative results. His blood was type O, Rh-positive.

Twenty-four hours after the antibiotic therapy was discontinued, on the fifth postoperative day, the patient had a chill and his temperature rose to 103 F (39.4 C); the pulse was then 140 and respirations 30 per minute, and blood pressure was 120/80 mm. Hg (fig. 1). The white blood cell count was 17,000 per cubic millimeter, with 86% neutrophils. Results of two blood cultures taken on that day and the following day were negative. Urine examination also gave a negative result. Blood urea nitrogen level was 46 mg.%. The patient was then given crystalline penicillin, 500,000 units every six hours. His temperature improved with this therapy, but the patient's condition remained toxic; the pulse was 110 and 120 per minute. It was then evident he was suffering from a severe infection. The white blood cell count had increased to 20,000 per cubic millimeter, with 83% neutrophils. On the ninth postoperative day, because the patient continued with severe tachycardia, tachypnea, fever, and vomiting for 48 hours, it was decided to use kanamycin (Kantrex). The first day he was given 1 Gm. but from then on a total of 3 Gm. per day was given for 12 days. When he complained of tinnitus the kanamycin dosage was reduced to 1 Gm. a day for the next three days. He received a total of 40 Gm. over the period of 16 days.

During the administration of the antibiotic daily urine examinations were carried out, but no major damage to the kidney could be detected. The hematological values became normal and the elevated blood urea nitrogen level, which was interpreted as indicating prerenal azotemia, dropped gradually. On his 10th postoperative day, 24 hours after kanamycin therapy had been started, the surgical wound began to drain profusely, and a culture of the exudate was positive for coagulase-positive Staphylococcus pyogenes var. aureus. This staphylococcus was sensitive to chloramphenicol, erythromycin, and kanamycin and resistant to eight other antibiotics.

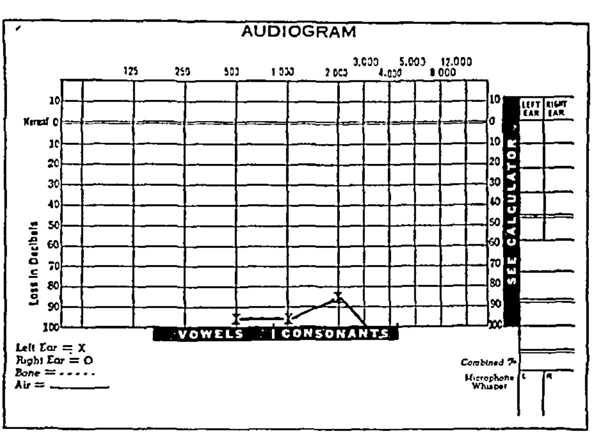

Fig. 2 (case 1).—Audiogram taken on 17th postoperative day.

On the 12th day of administration, the 22nd hospital day, after he had received 37 Gm. of kanamycin, he started having ringing of a high pitch in both ears. Twenty-four hours later he noted loss of hearing that rapidly increased so that in 48 hours he "heard nothing." The nasal mucosa was reddened, there was pus present in the tonsils, and bilateral cerumen was washed out. Both eardrums were retracted and a whitish deposit was noted at the posterior superior quadrant of the left eardrum. An audiogram made at this time (fig. 2) showed severe bilateral deafness. There was no discrimination whatsoever in hearing for speech even at 100 db. in either ear. On his 14th postoperative day the patient was taken to the operating room, the wound was reopened, and a large subhepatic abscess was found and drained. After this the patient's pulse and temperature gradually came down and his condition improved until his discharge after 30 days in the hospital.

There was no history of the patient's ever having received streptomycin or neomycin. The pathologist's report on a specimen from the stomach was hemorrhagic gastritis; no ulcer was found. The patient's progress has been followed for two months and he has been symptom-free from the gastrointestinal point of view, but the damage to the eighth nerve has continued, with total deafness (fig. 3).

Case 2.—A 62-year-old man came into the hospital because of urinary infection and renal failure. He had had repeated attacks of urinary infection since childhood, with several attacks of renal lithiasis. He had undergone a nephrectomy because of renal stones 12 years previously. He had been known to be hypertensive for the past three years.

Present Illness.—About four weeks before admission he developed a severe epistaxis, requiring posterior packing of the nose and surgical cauterization of the mucosa. His blood pressure was 200/130 mm. Hg, and the blood urea nitrogen level was 170 mg.%. Because urine culture gave a positive result he was given nitrofurantoin (Furadantin), with poor results, and then 1 Gm. of kanamycin twice a day. He received a total of 14 Gm. When the patient had received 12 Gm. he began to notice tinnitus, and although the drug therapy was discontinued he developed almost complete deafness in four days. Hearing was normal prior to treatment. Pus was found on pressure of the tonsils, and both eardrums were thickened and whitish. Crusts were present in the right nostril. An audiogram showed a severe hearing loss for the right ear (fig. 4), but an island of decibels for 1,000 cycles in the left. The patient received, besides kanamycin, vitamin K and a lipid-protein thromboplastic agent (Clauden) as the only other medicaments. He denied any previous ear trouble or ever having received streptomycin or neomycin.

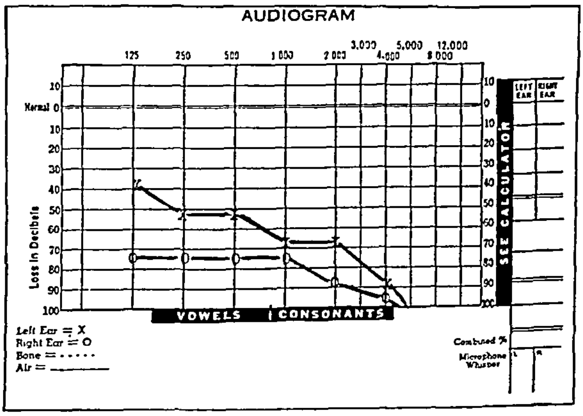

Fig. 3 (case 1).—Audiogram taken eight days after therapy with kanamycin was discontinued.

Physical Examination.—The patient looked ill, and his mucous membranes were pale and dry. Lungs were normal to percussion and auscultation. The heart was normal and blood pressure was 200/110 mm. Hg. The laboratory tests made on admission showed hemoglobin level to be 7.62 Gm.%; red blood cell count, 2,610,000 per cubic millimeter; white blood cell count, 6,950 per cubic millimeter, with eosinophils 6%, neutrophils 74%, lymphocytes 13%, and monocytes 7%. The red blood cell count showed some *polychromatophilia and* anisocytosis. Coagulation time was 8½ minutes, bleeding time 1 minute. His blood was type O, Rh-positive. The blood urea nitrogen level on admission was 86 mg.% and blood creatinine level, 5.1 mg.%. Serologic examination gave a negative result. Urine showed a specific gravity of only 1.005; there was 2+ albumin and the sediment showed white and red blood cells with occasional granular casts. The urine culture was positive for Staph. aureus, coagulase-positive and sensitive to chloramphenicol, novobiocin, and tetracycline but resistant to other antibiotics. The electrocardiogram showed slight abnormality which was interpreted as consistent with an elevated serum potassium level.

Course in Hospital.—The patient remained in this hospital for one week. He showed a daily low-grade fever and his blood pressure fluctuated between 160/100 and 200/110 mm. Hg. He received a transfusion of 500 cc. of blood and a 250-mg. dose of chloramphenicol every six hours. He was discharged slightly improved. When seen four months later he had severe signs of uremia and the deafness had continued with the same intensity.

CASE 3.—A 55-year-old woman stated that three months before admission she had begun to vomit and had epigastric distress without relation to food or time of day. When the attacks of vomiting recurred a physician found that she had hypertension. During the past six years she had had some dyspnea on exertion, and she had noted loss of weight in the past six months. We were unable to obtain a history of her having received streptomycin or neomycin.

Physical Examination.—On admission to hospital the patient was obese; her skin was dry and there was edema of the eyelids as well as the ankles. The blood pressure was 170/100 mm. Hg. The blood sugar level, which had been 230 mg.% two months before admission, was 105 mg.%. Blood urea nitrogen level was 68 mg.%. The urine showed a few leukocytes, red blood cells, and granular and hyaline casts. A urine culture was reported positive for Escherichia coli, sensitive to nitrofurantoin, kanamycin, chloramphenicol, and tetracycline.

Course in Hospital.—On her sixth hospital day, because of positive urine culture, she received 2 Gm. of kanamycin, then 1 Gm. each day for the next six days. The urine culture remained positive and on her 18th hospital day kanamycin therapy was resumed, 2 Gm. the first day and 1 Gm. on the three successive days. After receiving a total of 14 Gm. she complained of deafness, and, although the drug therapy was discontinued immediately, she rapidly developed total deafness. The audiogram was reported negative for both ears in air as well as bone conduction.

Comment

It is known that neomycin is nephrotoxic and neurotoxic[1] and that kanamycin has a similar chemical structure and similar antibiotic behavior, since there is complete cross-resistance between the two antibiotics[2]; therefore it seemed quite possible that kanamycin would be toxic for the kidney as well as for the ear. It is interesting that kanamycin has an incomplete cross-resistance with another neurotoxic antibiotic, streptomycin. The literature indicates that kanamycin has a definite toxicity for animals[3] as well as for man, producing damage to the kidney,[4] affecting the tubular and glomerular function,[5] and damaging the eighth cranial nerve.[6] At present the exact toxic dosage of kanamycin has not been established, but it seems to depend not only on the total amount administered but also on the dose given per day.

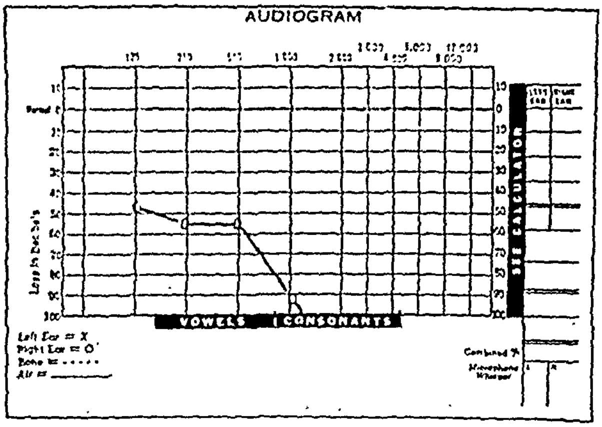

Fig. 4 (case 2).—Audiogram taken two weeks after therapy with kanamycin was discontinued.

Bunn and Baltch,[7] reporting on 15 patients, observed no side-effects from kanamycin when 1 Gm. was given daily for 3 to 17 days. The same authors observed the toxicity to be of a minimal order when the drug was given for less than three weeks in doses that varied between 0.5 and 3.0 Gm. per day. Above this level they observed eosinophilia, urinary abnormalities, and damage to the eighth nerve, particularly when the total amount of kanamycin received by the patient was between 40 and 50 Gm.[4a] Other investigators[8] report no toxic effects with daily doses of 1 to 2 Gm., but if the time of administration is prolonged to six months, even though the daily dose is reduced to 0.5 Gm., damage to the auditory nerve is produced.[4b] Donomea[6a] found audiometric impairment in 20% of the patients who received over 6 Gm. of kanamycin per week, but he was able to reduce this toxicity to 4% if the amount of the antibiotic was less than 6 Gm. per week.

In our report, in case 1, kanamycin was administered in the maximum recommended dose. The patient had a prerenal azotemia, as proved by the return of the blood urea nitrogen level to normal values. As soon as the intra-abdominal abscess was drained, and while the administration of kanamycin continued, there was no decrease in the urinary output and the blood creatinine level remained normal. The total amount of kanamycin that the patient received was 40 Gm. in 16 days, and the symptoms of injury to the eighth nerve appeared when he received 37 Gm.; therefore, the ototoxicity became evident before the level that has been pointed out as toxic was reached.[7]

In the other two cases presented here serious renal lesions existed before the administration of kanamycin. In case 2 the total amount of kanamycin given to the patient was 14 Gm. in seven days, with impairment of hearing becoming evident after he had received 12 Gm. In case 3 the damage seemed more marked, since the total amount of the antibiotic was only 14 Gm., administered in two periods, with an interval of five days of no kanamycin administration. The signs of deafness became noticeable during the second course of treatment with only 4 Gm. of kanamycin. This last case is suggestive of a hypersensitivity to the antibiotic or a cumulative toxic effect due to the patient's renal failure.

Common to our three cases was the progressive damage to the auditory nerve, which appeared to be irreversible and which continued even though kanamycin therapy was discontinued at the first signs of damage.

The number of cases presented here is too small to permit conclusions to be drawn, but the accumulation of this type of information should establish the position of this new antibiotic in clinical practice and clearly determine its limitations.

HAZARDS OF MERCY.—From time to time reports appear in the newspapers of what are described as "Mercy Flights." They are usually undertaken to convey someone from an outlying area to a larger centre where he can obtain urgently needed special medical attention or to rescue someone in danger of his life, for example, from flood. A number of such flights have ended in disaster, perhaps with loss of the lives of all concerned, and no doubt many people have wondered what lay behind these tragedies. . . . Since the majority of Mercy Flights intimately concern members of the medical profession, it is vital that they should understand what such flights involve and the conditions under which they may be undertaken. . . . While medical emergencies can arise at any time, the aircraft mostly used in this work can be flown with normal safety only in daylight and fair weather. Most medical or ambulance flights take place under visual flight conditions and are perfectly normal operations with an excellent safety record. It is the minority which become Mercy Flights that constitute the problem. The difficulties outlined here could be reduced by an understanding on the part of the doctor of the pilot's problems, and by a readiness to discuss with the pilot the medical aspects of a flight proposed at night or in bad weather—that is, by definition, a Mercy Flight. —Mercy Flights and Their Safety, editorial, *The Medical Journal of Australia,* Jan. 24, 1959.

CONSCIOUSNESS AND PAIN DURING APPARENT SURGICAL ANESTHESIA

REPORT OF A CASE

Thomas D. Graff, M.D.
and
Otto C. Phillips, M.D., Baltimore

A patient underwent an operation under general anesthesia which included the use of succinylcholine and intravenously given lidocaine, with assisted respiration. After recovery she gave evidence of having been intermittently conscious during the three-hour period of supposed anesthesia and stated that she had suffered extreme pain during much of the operation. An awareness that such an extreme in pain reflex threshold may rarely exist in patients undergoing operative procedures should caution us to be more appreciative of the subtle signs suggesting an inadequate state of anesthesia. This is particularly applicable when respiratory reflexes and other types of response are obviated by the use of neuromuscular blocking agents.

The introduction of curare as a neuromuscular blocking agent in clinical anesthesia by Griffith and Johnson[1] in 1942 set the stage for radically different concepts in the practice of surgical anesthesia. Here was a means whereby satisfactory anesthesia could be offered to the most demanding of surgeons without the necessity of maintaining high blood and brain tissue levels of inhalation or intravenous anesthetic agents. The demonstration by Foldes and co-workers[2] of the close control of neuromuscular paralysis afforded by a continuous infusion of dilute succinylcholine gave more widespread popularity to and promoted acceptance of this school of practice. In 1955 Artusio[3] introduced the technique of ether analgesia and described the homeostatic benefits derived by maintaining a level of anesthesia at which the patient was capable of responding to questions and of discriminating subjective senses of taste and color.

The combination of minimal central nervous system narcosis plus neuromuscular blockade has received increasing acceptance by clinical anesthesiologists throughout the United States and abroad during the past 10 years. We have utilized this form of anesthesia in several thousand surgical and gynecologic operations and have been favorably impressed with it as a technique providing a smooth course of surgical anesthesia, with a minimum of side-effects and a short postoperative waking time. After such an anesthetic procedure there occurred recently on our service a complication which brought forcibly to our attention a potential hazard involved in this concept of anesthesia, which we feel is of sufficient importance to be reported.

Report of a Case

The patient was a 40-year-old woman who entered the hospital with the diagnoses of cystocele and rectocele. She was scheduled for a vaginal hysterectomy and an anterior and posterior colporrhaphy. Her operative history included a tonsillectomy as a child and an appendectomy at the age of 16 years, both under gas-oxygen-ether anesthesia. She had had four vaginal deliveries. For the first three of these she had had gas-oxygen-ether anesthesia, and for her fourth and last delivery a saddle-block technique had been used. During one of the pregnancies she had been given paraldehyde in an early and quiescent phase of labor, had become agitated, and had had intense and vivid recollections of her pain after this medication. Administration of codeine and meperidine at various other times resulted in extreme episodes of nausea and vomiting. Administration of erythromycin, two years prior to admission, had caused a skin eruption. Three years prior to admission she was hospitalized with a tentative diagnosis of pericarditis, but studies did not confirm this impression and it was decided that the presenting symptoms were emotionally based.

Physical findings on the present admission were normal except for the pelvic and perineal disease for which the operation was to be performed. Her hemoglobin concentration was 11.7 Gm. % (81%), and white blood cell count 6,800 per cubic millimeter with 48% polymorphonuclear cells, 50% monocytes, and 1% basophils. The hematocrit was 38%. Blood glucose level was 86 mg.%, blood urea level 35 mg.%. Urinalysis revealed nothing abnormal; specific gravity was 1.013.

The patient was given, as bedtime sedation the evening before the operation, secobarbital and amobarbital (Tuinal), 100 mg., and perphenazine (Trilafon), 4 mg., each by mouth. In view of her his-

---

From the Anesthesiology Department, Hospital for the Women of Maryland.

tory of side-reactions to opiates no narcotic was given preoperatively, the medication consisting of 5 mg. of perphenazine and 0.4 mg. of atropine intramuscularly one hour before the induction of anesthesia. Bearing in mind also the history of recent emotional problems it was decided that a general anesthetic would be indicated for the anticipated operative procedure.

Anesthesia was induced with intravenous administration of thiopental, 200 mg. in a 2% solution. The patient was given a continuous intravenous infusion containing 0.1% lidocaine and 0.025% succinylcholine. Nitrous oxide and oxygen at a 4-liter and 2-liter flow, respectively, in a semiclosed circle-absorber system was then administered under a mask. Respirations were spontaneous but assisted throughout the course of anesthesia. The operative procedure lasted two hours and 50 minutes and the anesthesia three hours and 10 minutes. During this time a total of 400 mg. of thiopental, 500 mg. of succinylcholine, and 2 Gm. of lidocaine were used. A no. 3 oropharyngeal airway was inserted early during the procedure and removed at the end before the patient left the operating room. The systolic blood pressure was 120 mm. Hg before the induction of anesthesia and ranged between 115 and 130 mm. Hg during the entire procedure. The pulse rate ranged from 84 to 100 per minute. The blood loss was appreciably more than usual, and this was commented on by the members of the operating team.

Two 500-cc. units of blood were administered during the operation. The color of the patient and of the blood was good at all times and the anesthesia progressed uneventfully. It was noted that there were occasional episodes of resistance to inspiratory assistance. At one point during the operation the patient (in a lithotomy position) suddenly moved her right leg.

The patient was responding and talking to visitors within 10 minutes of leaving the operating room. Her blood pressure remained a little low during much of the afternoon (88 to 100 mm. Hg systolic), but the pulse was slow and her skin was warm and dry, although she appeared slightly pale. There was little nausea, and no vomiting was noted by the nurse or remembered by the patient during the postoperative period. She received during the first three days a total of 25 mg. of morphine and 10 mg. of perphenazine, in divided doses.

Despite this apparently uneventful anesthetic course the patient had a most unpleasant experience to relate to the surgeon and the anesthesiologist. She had been intermittently conscious and unconscious during the three-hour anesthetic period. She volunteered the information that an airway had been inserted in her mouth and removed at some later time. She reconstructed details pertaining to the discussion of the blood loss and the decision to start administration of the second unit of blood. She also experienced dull, unbearable pelvic, lower back, and perineal pain during much of the operation.

Comment

There is little doubt in the minds of the attending physicians that the patient was conscious during phases of this procedure and suffered considerable discomfort. As this was the first such case in our experience, we have reviewed critically the management of the entire anesthetic procedure including the preanesthetic medication, the agents and proportions used, the mechanical accuracy of the anesthesia apparatus, the background of the patient, and our own ability to evaluate the adequacy of anesthesia under the situation described.

Galla and co-workers[4] have recently reevaluated the traditional signs of anesthesia as they might apply to newer anesthetic agents and techniques. Nearly all of our signs of anesthetic depth are dependent on the muscular response to some type of stimulus, whether exogenous, provoked by the observer, or endogenous, as a result of physiochemical changes at the vital centers. While the patient is under neuromuscular blockade such signs are either eliminated or dampened to the point where they become less easily recognized. Galla and co-workers stressed the importance of two signs indicating light planes of anesthesia in the patient under curare anesthesia. The first of these is increased resistance to inflation of the lungs, which is associated with Courtin and co-workers' electroencephalographic level 1[5]; the second is pupillary dilatation in response to surgical stimulus. This same author pointed out that alternative etiological factors leading to pupillary dilatation are excessively deep planes of anesthesia and anoxia.

Artusio[3] has demonstrated that in plane 2, stage 1 of ether analgesia, although a patient is still responding to questioning and reacting to surgical stimulus with gross movements, there is complete amnesia on postoperative questioning. Facial grimacing and movements of an extremity are signs frequently seen during analgesic techniques, whether the primary anesthetic agent is nitrous oxide or ether.

In the case described in this report pharyngeal and corneal reflexes were absent, and respirations were depressed to the point of requiring some assistance. These several signs suggested a surgical depth of anesthesia. There was maximal pupillary constriction throughout the course of the anesthesia, which has been a consistent finding in our patients who receive intravenous thiopental, succinylcholine, and lidocaine combined with a nitrous oxide and oxygen inhalation anesthetic, and which would not have suggested an unduly light plane of anesthesia. Any degree of pupillary dilatation would have caused us to be concerned about the adequacy of our ventilating technique or about the possibility of an adverse response of the patient's cardiovascular and cerebrovascular mechanisms to a surgical or an anesthetic insult.

Although the patient was breathing spontaneously throughout the anesthetic course, there were periods of increased resistance to lung inflation while inspiration was assisted and occasional episodes of sudden change in rate and depth of breathing. These phases of her respiratory pattern were the only indications of light anesthesia. In addition, as was noted in the protocol, the patient made a sudden movement of her right leg at the time the surgeon made his initial incision in the posterior vaginal mucosa to repair the rectocele. This occurred 30 minutes before the end of the entire operative procedure. Such a plane of anesthesia was not considered undesirable; it caused no impediment to the surgical procedure and allowed for full compensatory response to the not inconsiderable blood loss being suffered by the patient. With the basal narcosis of intravenously given thiopental and an apparent metering of two-thirds nitrous oxide in a total flow of 6 liters, it was felt that there was no chance that the patient would not receive complete analgesia and amnesia for the operative procedure.

A review of the present case serves to caution us that, in our efforts to make possible surgical intervention with a minimum of homeostatic disturbance, the anesthetic or pain-reflex threshold of the patient may be at such a level that we are actually administering inadequate amounts of depressive agents to obtain the desired degree of analgesia and amnesia. It should be emphasized that signs of unduly light anesthesia may be most subtle and that the analgesic techniques utilized may be accompanied by the inherent risk of a conscious and uncomfortable patient. The use of the neuromuscular blocking agents amplifies the chances of this situation occurring. Perhaps the addition of an opiate to the preanesthetic medication may have sufficed to have given the patient the required amount of basal narcosis. The importance of the preoperative opiate in a nitrous oxide anesthesia has been stressed by Clement,[6] although in recent years much has been written concerning the iniquities of prescribing opiates to the patient going to surgery.[7] A larger dose of thiopental than the 400 mg. used for the three-hour procedure would certainly have been justified and could have induced the additional anesthetic depth necessary. However the deeper anesthesia is accomplished, greater concern when confronted with the signs of light anesthetic planes may help to avert subsequent experiences such as the one just described.

Summary

A patient under apparent anesthesia for a prolonged perineal operation suffered indisputable phases of consciousness and extreme pain. Pertinent aspects of the analgesic techniques in anesthetic management include a consideration of the interpretation of the signs of anesthesia as they might apply to our new anesthetic agents and methods, especially the role of the neuromuscular blocking agents in affecting the signs of anesthetic depth. Although the minimal effect on homeostasis of the newer anesthetic techniques is of recognized value, an awareness of the possibility of an anesthetic experience such as the one described should serve to make us pay greater heed to signs of light planes of anesthesia.

NAUSEA AND VOMITING IN THE IMMEDIATE POSTANESTHETIC PERIOD

Andre Smessaert, M.D., Claire A. Schehr, M.D.
and
Joseph F. Artusio Jr. M.D., New York

Factors that might determine the incidence of nausea and vomiting were sought in a study of 1,602 patients recovering from general anesthesia. Vomiting was somewhat less frequent in older patients than in younger ones and much less frequent in men than in women. Comparisons between anesthetics were difficult because the type of operation influenced the choice of anesthetics, but under the conditions of this study the use of ether was followed by a slightly lower incidence of vomiting (23.3%) than was the use of cyclopropane (24.1%). Endotracheal intubation and administration of relaxants had no appreciable effect, but insertion of a gastric tube reduced the incidence of vomiting from 25.3 to 15%.

Every general anesthesia is composed of three parts: induction, maintenance, and emergence or recovery. Many clinical and laboratory studies on the first two phases of anesthesia have been reported, resulting in improvements in anesthetic techniques. Patients can now be anesthetized for surgery considered impossible only a few years ago. These improved results are related to new agents, improved techniques and apparatus, and increased knowledge in the fields of physiology, pharmacology, and chemistry related to anesthesia. In contrast to this, relatively little work has been done in relation to the period of emergence from anesthesia.

The introduction of the postanesthesia recovery room has been a significant advance in postoperative care of the surgical patient. Patient safety has been increased by the presence of specially trained nursing personnel familiar with patient care during this critical period. In 1899 Blumfeld wrote, "A patient's dread of operation is often due more to his fear of anesthesia than to the operation itself."[1] The fear of anesthesia is mostly caused by the anticipation of the unpleasantness of the postanesthesia recovery phase. It matters little to the average patient that he received a skillful anesthesia, requiring possibly several hours of constant vigilance and care in order to provide and maintain normal physiology throughout an operative procedure. Rather, the patient's concern is associated with what he experienced when he regained consciousness, and frequently the difficulties of this period are ascribed to anesthesia.

Dripps[2] observed in 1949 that there was "little significant information on such a commonplace problem as the incidence of nausea and vomiting following the administration of an anesthetic." Because of the many variables involved, such as premedication, anesthetic agent and method of administration, duration of anesthesia, type of operation, and age, sex, physical status, mental status, constitution, and habitus of the patient, the task of studying the postanesthesia recovery is a difficult one. This investigation was undertaken in order to collect more information on this important period.

The study was divided into three major parts: observations related to nausea and vomiting, observations related to the mode of recovery, and observations related to blood pressure. This particular report deals only with the observations concerning nausea or vomiting. All data obtained were analyzed and correlations were made between some of the many variables related to anesthesia and surgery; specifically, the possible relationship between physical characteristics of the patient, age, sex, and body structure, and type and duration of operation.

Procedure

Special study sheets, composed of two parts, were filled out in conjunction with the anesthesia record of each patient. The first section was completed by the person administering the anesthesia. For classification of the structural type the following criteria of body structure based on Kretschmer's[3] work were used: narrow, slender (leptosome); rounded, chubby (pyknic); muscular, well-developed (athletic); and with grossly abnormal proportions or deviations (dysplasic). These records then accompanied the patient to the recovery room, where they were completed by the recovery room personnel under the supervision of an anesthesiologist. The recovery room nursing staff had no precise knowledge of the objectives of this study, so their observations may be presumed to be unbiased.

Notations concerning nausea and vomiting were based only on objective signs. Vomiting was recorded whenever the expulsive efforts produced even a small amount of material. Nausea was re-

---

corded when a patient was complaining of a desire to vomit or when expulsive but unproductive vomiting movements were observed. Nausea is a subjective experience which may or may not be associated with vomiting or retching; retching is defined as spasmodic contractions of the respiratory and abdominal musculature without expulsion of any material. We use the term nausea in this paper to designate the two phenomena. The patients were asked no questions related to nausea and vomiting, in order to avoid any suggestion in the matter. The patients were discharged from our recovery room when they were alert, with stable vital signs, and oriented as to time and place. The average time for this ranged from two to three hours.

The completed data sheets were coded and the results reported on IBM cards; these cards were used later for tabulation, correlation, and analysis. Complete observations and data were obtained on 1,602 patients of all ages. Of these 752 were males and 850 were females. Five age groups were used in the study: group 1, aged 10 and under, comprising 152 patients, 101 boys and 51 girls; group 2, aged 10 to 17, comprising 64 patients, 44 boys and 20 girls; group 3, aged 18 to 49, comprising 623 patients, 194 men and 430 women; group 4, aged 50 to 65, consisting of 483 patients, 250 men and 232 women; and group 5, aged over 65, consisting of 280 patients, 163 men and 117 women.

Table 1.—*Distribution of Anesthetic Agents by Age and Sex of Patient*

18-49	86	38	48	88	41	47	329	70	259	120	44	76
50-65	99	65	34	108	51	57	162	84	78	108	49	59
over 65	78	57	21	85	47	38	65	29	36	51	30	21
Total	272	166	106	296	150	146	580	199	381	294	134	160

Ninety-seven per cent of the patients were given premedication with barbiturate and belladonna preparations, usually amobarbital (Amytal) sodium and atropine. Only 3% received an opiate in lieu of or in conjunction with the barbiturate or belladonna. Four anesthetic agents were used: a combination of thiopental and nitrous oxide; ether; cyclopropane; and cyclopropane with ether. Their distribution is reported in table 1.

Duration of Anesthesia.—In 408 patients (153 males and 255 females) the duration of anesthesia was one hour or less; in 479 patients (249 males and 230 females) it was one to two hours; in 287 patients (123 males and 164 females) two to three hours; in 172 patients (74 males and 98 females) three to four hours; and in 104 patients (52 males and 52 females) the procedure took over four hours. Results were analyzed by means of the chi-square test; the following criteria were used for p values: $p<0.01$ considered significant, $0.01<p<0.02$ considered of borderline significance, and $p>0.02$ considered insignificant.

Results

Data concerning patients of age group 1 are included only in the general results (table 2), because we believe that the reactions of children should not be evaluated with those of adults. Results related to nausea are not reported in several tables for purposes of simplification; results concerning nausea always paralleled those obtained for vomiting.

Table 2.—*Incidence of Nausea and Vomiting in Relation to Age and Sex*

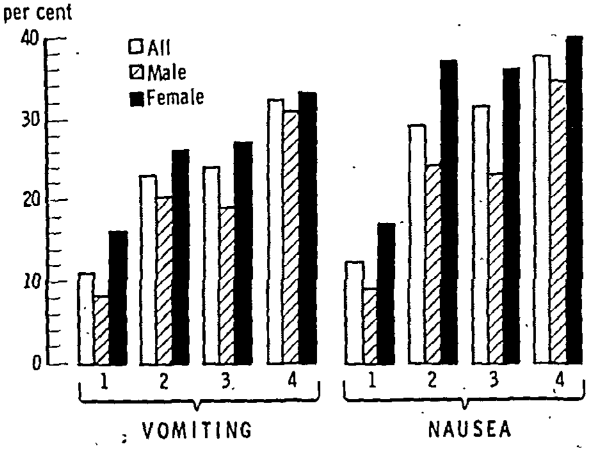
There was a significant difference in the incidence of vomiting related to anesthetic agents (see figure); for males it was more pronounced than for females ($p<0.01$). The incidence of vomiting (table 2) varied significantly with age, especially in males ($p<0.01$). The incidence of vomiting in males was significantly different from that in females in patients over 11 years of age ($p<0.01$). The incidence of vomiting did not vary significantly with body type (table 3) in either the males or the females ($0.02<p<0.05$ for males; $0.2<p<0.3$ for females). The incidence of vomiting varied significantly with site of operation (table 4) for both sexes ($p<0.01$).



Vomiting and nausea in relation to anesthetic agent used. 1=thiopental and nitrous oxide combination, 2=ether, 3=cyclopropane, and 4=cyclopropane with ether.

There appeared to be a constant upward trend in the incidence of vomiting as the duration of the procedures increased (table 5), but the incidence was only of borderline significance ($0.01<p<0.02$).

TABLE 3.—*Distribution of Structural Types by Sex and Relation to Incidence of Vomiting*

Structural Type	Distribution				Incidence of Vomiting					
	Total		M	F	Total		M		F	
	No.	%			No.	%	No.	%	No.	%

Athletic	492	33.9	333	159	122	24.8	81	23.3	41	25.7
Pyknic	396	27.3	88	308	109	27.5	18	20.4	91	29 5

There was a significant relationship between the incidence of vomiting and the presence of a gastric tube ($p<0.01$). Among patients without gastric tubes the incidence was 25.3 and among those with tubes 15%. The incidence of vomiting with endotracheal intubation was 24.4 as against 22% without intubation. With the use of relaxants the incidence was 21.5 and without relaxants 24%.

Comment

A review of the pertinent literature shows that there has been a definite trend in recent years toward a lower incidence of postoperative nausea and vomiting after general anesthesia. Studies reported as recently as 1929 indicate an incidence well above 50 and sometimes as high as 80%.[4] In contrast, Dent and associates[5] reported a low percentage of 27.5 in 1955; Burtles and Peckett[6] 32 in 1957; and Bonica and associates[7] reported a percentage of 30.5 in 1958. Waters[8] reported 40.6% in his study of 1936 but only 35.5% in 1951. In our study the over-all incidences were 24.3% for vomiting and 29.5% for nausea (table 2). It should be pointed out that a number of patients emerged very rapidly from anesthesia, and that some of these patients may have vomited while still in the operating room or on their way to the recovery room. Had these cases been included in the results they would have increased the number of cases of vomiting reported in the recovery room by 15%.

TABLE 4.—*Incidence of Vomiting in Relation to Sex and Type of Surgery*

The anesthetic agent appears to be a factor of major importance in the incidence of postoperative nausea and vomiting (see figure). Results reported in the literature vary widely. Previous reports indicated an 80% incidence associated with diethyl ether anesthesia.[9] In more recent work the trend was lower and averages varied between 30 and 60%.[10] For cyclopropane the results vary between 24 and 50%.[11] Combined thiopental and nitrous oxide has always been reported as giving the lowest incidence, between 14.5 and 30%.[12]

The present study indicates that nausea and vomiting occur in 23.3% of patients receiving ether and in 24.1% of those receiving cyclopropane. The general belief that ether causes more nausea and vomiting than other inhaled anesthetic agents was not substantiated by the results. However, nausea and vomiting after anesthesia with ether are as a rule more persistent than after that with cyclopropane. The incidence after combined thiopental and nitrous oxide anesthesia (11%) was far lower than after any other agent.

The age of the patient (table 2) appeared to influence the incidence of postanesthetic vomiting, particularly in males; for both sexes, however, there was a definite tendency toward lower incidences among older patients. The sex of the patient is a factor of major importance. A higher incidence among females was observed in nearly all circumstances, regardless of the anesthetic agent used. Several other authors have made the same observation.[13]

The site of operation (table 4) has an important role in the relative occurrence of emetic symptoms. This is a generally accepted observation; however, the respective influence of different types of surgery is a controversial subject, especially with respect to intra-abdominal operations.[14] Knapp and Beecher found little difference between intra-abdominal and other operations; Bonica and associates found a high incidence of vomiting after abdominal surgery; Burtles and Peckett found a relatively low incidence; and our results were very low. The divergence of these results obviously indicates that this complex problem is not solved.

Head and neck operations and particularly those on the thyroid were followed by a high incidence of emetic symptoms; this is in accord with the findings of other investigators.[15] The low incidence after operations on the urinary tract, also noted by Burtles and Peckett, is partly explained by the fact that the vast majority of patients undergoing this type of surgery are men over 50 years of age and partly by the fact that the thiopental and nitrous oxide combination was the anesthetic agent in 52% of the cases.

Several investigators have expressed the belief that the duration of a procedure could influence the incidence of postanesthetic nausea and vomiting.[10] Knapp and Beecher were unable to confirm this opinion. The results obtained in this study (table 5) appear to give some support to it. However, it is necessary before formulating a definite conclusion concerning the influence of duration of anesthesia to analyze certain factors which could bias the results. Different types of operations in relation to duration and age group did not appear to influence the findings. However, the various anesthetic agents do influence postoperative vomiting; consequently, it was important to correlate agent and duration. The distribution of agents used in anesthesias lasting one hour or less was as follows: combined thiopental and nitrous oxide, 135; ether, 28; cyclopropane, 206; and cyclopropane combined with ether, 35. The expected incidence of vomiting calculated for this distribution is 20%; this is very close to the 18.8% obtained in this study. The expected incidence for anesthesias lasting up to two hours is 22.5%; the result of this study showed it to be 21.6%. However, for the longer anesthesias the results were a little above the expected incidence; for anesthesias over three hours, 30 as against 26%, and for those over four hours, 32.6 as against 28%.

The important factor in the analysis is the fact that combined thiopental and nitrous oxide was used in 33% of the anesthesias of one hour's duration, in 22% of those of two hours' duration, in 9% of those of three hours' duration, in 5% of those of four hours' duration, and in only 1% of those lasting more than four hours. This relatively high percentage of thiopental and nitrous oxide anesthesia in the shorter procedures was a factor in the lower average incidence of emesis in these cases. The conclusion is that duration of anesthesia appears to have little influence on the incidence of nausea and vomiting; however, it should be noted that there is an upward trend in the incidence of vomiting as duration increases.

The concept that a gastric tube provides a beneficial effect is substantiated by the data of this study. This has also been the experience of several other investigators. The results in relation to endotracheal intubation and the use of relaxants indicate that these factors have no appreciable influence on postoperative vomiting.

Summary

Observations during the immediate postanesthesia phase were recorded in 1,602 patients. The over-all incidence of vomiting was 24.3%; the incidence in males was significantly different from that in females. The influence of body structure was not marked for either sex, but emesis was less frequent in the older age groups.

Anesthesia with use of combined thiopental and nitrous oxide was followed by vomiting in 11% of the cases. Ether and cyclopropane anesthesia were followed by vomiting in 23.3 and 24.1% of the cases respectively. The incidence of vomiting varied significantly with the site of operation for both sexes. The duration of anesthesia was not important in relation to postoperative nausea and vomiting, but there appeared to be an upward trend as duration increased. The gastric tube had a favorable effect, while endotracheal intubation and the use of relaxants had no appreciable influence on vomiting.

AGRANULOCYTOSIS CAUSED BY PHENOTHIAZINE DERIVATIVES

Donald R. Korst, M.D., Ann Arbor, Mich.

Agranulocytosis has sometimes followed the use of chlorpromazine and promazine, and there is reason to assume that it can also be induced by sufficient amounts of other drugs of the phenothiazine group. In most of the known cases this reaction occurred during the first 15 weeks of drug administration. In the cases here described two men, aged 72 and 41 years, had received chlorpromazine and promazine respectively; a third, aged 49, had received both drugs. At the height of the agranulocytosis the first patient had only 2% neutrophils and a total leukocyte count of 900 per cubic millimeter; in the other two patients the neutrophils vanished. Evidence in these cases indicated that the reactions represented individual idiosyncrasies to cumulative doses of the drugs and that fatalities can be prevented by sufficient alertness and prompt recognition of incipient neutropenia. The three patients recovered without signs of residual damage.

That a specific drug reaction could cause granulocytopenia was demonstrated in 1934 by Madison and Squier[1] and confirmed by Sturgis and Isaacs.[2] Both groups showed that small test doses of aminopyrine were the etiological agent in patients recovered from agranulocytic angina. The phenothiazine ring (see figure), containing sulfur and nitrogen, is toxic to bacteria, insects, and helminths; is present in a veterinary vermifuge; and is a constituent of the parent substance of thionine dyes such as methylene blue. In humans, phenothiazine induces hemolytic anemia, toxic hepatitis, skin irritation, and photosensitization. The first derivative which was found to be pharmacologically useful is chlorpromazine, which was introduced in 1952 in France. Its first trade name (Largactil) was designed to indicate its large action and many uses. This drug is similar structurally to promethazine (Phenergan) but lacks antihistaminic properties. At the present time, there are six other derivatives in use which have actions similar to chlorpromazine (see figure). Not included in this list are the most recent drug, trimeprazine (Temaril), which is similar to phenergan and has antihistaminic properties, and the tranquilizers thioridazine (Mellaril) and trifluoperazine (Stelazine). Reports since 1954 indicate that agranulocytosis is a side-effect of chlorpromazine therapy, and this reaction has also been noted with promazine, promethazine, prochlorperazine, perphenazine, and mepazine.

Chlorpromazine

A review of 58 cases from the literature and one case reported here provides the basis for some generalizations on the nature of agranulocytosis associated with chlorpromazine therapy. Reviews[3] provide information on 32 of the cases, and the remainder have been reported singly. The incidence of chlorpromazine agranulocytosis may be as high as three cases in 1,000 patients.[4] Data from 59 cases given in table 1 show the mean and the range. In most cases reported the patients had been given neuropsychiatric diagnoses; use of chlorpromazine in mental health institutions has undoubtedly influenced the reported mean age of 54 years (range

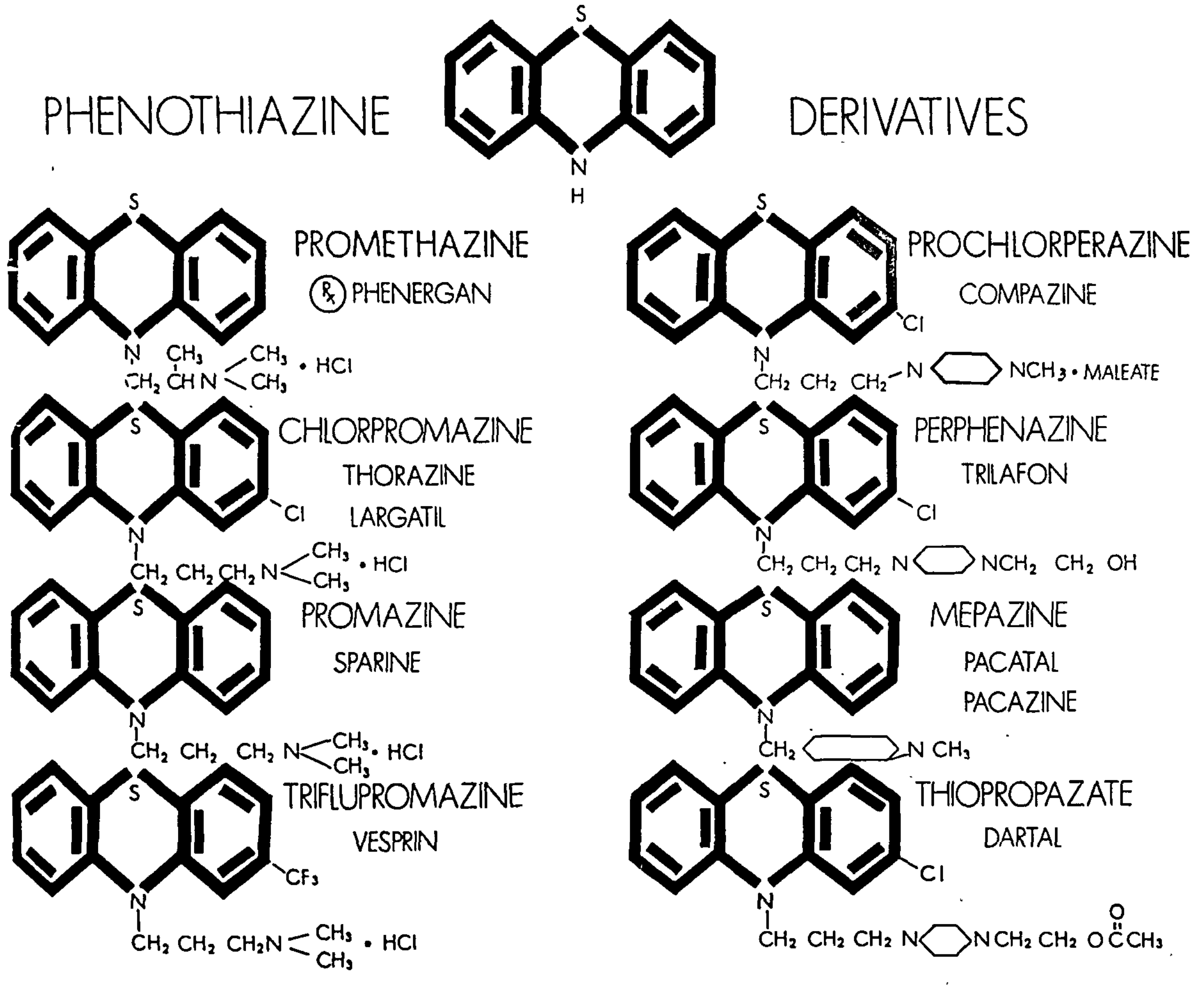
Assistant Professor of Medicine, University of Michigan Medical School, and Chief, Radioisotope Service, Veterans Administration Hospital.

Read, in part, before the regional meeting of the American College of Physicians, Traverse City, Mich., Sept. 19, 1958.

26 to 88 years). A great difference in sensitivity of patients is evidenced by the range of doses (from 1 to 52 Gm. [mean, 12.3]) of total drug administered on consecutive days prior to the reaction. The mean number of days of consecutive administration was 50 (range, 13 to 171), with a standard deviation of 26 days. This would suggest that two-thirds of the reactions can be expected to develop during the first 76 days and 95% during the first 15 weeks of drug administration. No other drug was administered concurrently in 35 cases, and chlorpromazine was the only phenothiazine derivative given in the remainder.



Of the entire group, 31 received hormone therapy in the form of ACTH, prednisone, or cortisone as well as antibiotics. The remainder received antibiotics alone. Steroid therapy did not seem to influence either mortality or recovery time. Twenty-two deaths with agranulocytosis were recorded. In general, about 10 days elapse after development of agranulocytosis and withdrawal of the drug before the leukocyte count returns to normal. The bone marrow "responds" (i. e., begins to recover) at least one week before the leukocyte count becomes normal. The time before return to normal or elevated total leukocyte levels has ranged in various reports from 5 to 16 days.

Promazine

Eleven cases plus one case here have been reported of agranulocytosis associated with promazine therapy.[5] Ages of patients and mean total dose are quite similar to those for chlorpromazine (table 1). From the experience in a few cases, it would appear that 95% of the reactions occur during the first 11 weeks of therapy. Three deaths have been reported, and the results of corticosteroid therapy and the recovery trends are also quite similar to those for chlorpromazine agranulocytosis. Bone marrow changes in cases of agranulocytosis after use of both these drugs are the same. Either there is almost complete absence of granulocytic elements or, if recovery has begun, there is predominance of progranulocytes or myelocytes. Erythropoiesis and thrombopoiesis have usually been reported as normal, except for approximately 16 cases in which the marrow findings were described as showing pancytopenia.

Other Derivatives

There is insufficient information on agranulocytic reactions to some of the other derivatives to permit any distinctions to be made. Mepazine agranulocytosis in four cases has followed a pattern similar to that of disease after chlorpromazine and promazine. A patient who had recovered from a reaction to chlorpromazine was shown to be sensitive to prochlorperazine and promazine.[3c]

Report of Cases

CASE 1.—A 72-year-old male was transferred on Sept. 22, 1957, from a mental institution to the Ann Arbor Veterans Administration Hospital with diagnoses of schizophrenia and acute appendicitis. Prior medication had included intermittent use of antibiotics, phenobarbital, reserpine, occasional injections of meperidine (Demerol), and intermittent injections of chlorpromazine during July and August, 1957. The patient had received chlorpromazine orally, 50 mg. four times a day intermittently from July 14, 1957, until his admission, for a total dose of 7.8 Gm. (table 2). Normal blood values were reported on July 15. Abdominal rigidity and tenderness in the right lower quadrant were present on admission, with 2 to 3+ pitting edema of both lower extremities. His temperature was 102 F (38.9 C). Blood values on admission were as follows: hemoglobin level, 13.5 Gm. per 100 cc.; hematocrit, 43.5%; leukocytes, 900 per cubic millimeter, with 2% neutrophils, 32% small lymphocytes, 58% large lymphocytes, and 2% plasmacytes; reticulocytes, 1%; and platelets, normal in number. His blood type was A negative, Rh positive. Appendectomy performed on the day of admission revealed a mucocele and atypical hyperplasia of the appendix mucosa without inflammation. Sternal marrow aspiration on Sept. 23 yielded a hypoplastic specimen with no mature granulocytic elements and only an occasional myelocyte. There appeared to be diminished erythropoiesis and number of megakaryocytes.

Inflammation of the pharynx developed, and rales were heard in the lower lung fields; he was treated with erythromycin, 1 million units of penicillin daily, and 1 Gm. of streptomycin daily. The febrile course continued from Sept. 22 through Sept. 30, when there was defervescence. Another sternal marrow examination on Sept. 26 revealed hypocellularity with rare occurrence of metamyelocytes and no over-all increase in myelopoiesis. The hemoglobin level was 12.2 Gm. per 100 cc. and leukocytes were 1,200 per cubic millimeter, with 5% neutrophils plus Türk's irritation cells. On Sept. 30 the leukocyte count was 5,250 and on Oct. 1, the day of defervescence, it was 11,200 per cubic millimeter, with 50% neutrophils. On Oct. 1, an aspirated specimen of sternal marrow was hypercellular, with marked increase in granulopoiesis and predominance of myelocytes. Use of antibiotics was discontinued, and the patient's recovery was uneventful. The leukocyte count continued to rise until Oct. 7, when it was 20,000 per cubic millimeter, with 82% neutrophils. It then gradually declined over the next 10 days to 9,000 to 10,000. Subsequently, the patient underwent transurethral resection of the prostate for benign hypertrophy. He received test doses of chlorpromazine (as shown in table 2) without significant reaction. The patient was last seen in January, 1958, when he was doing well, and his blood values were all within normal limits.

§ S.D.: standard deviation.

CASE 2.—A 41-year-old male with a diagnosis of schizophrenic reaction was transferred to this hospital on Oct. 14, 1957. Physical examination was within normal limits. Laboratory studies were normal, with 6,600 leukocytes per cubic millimeter and a hemoglobin level of 14.4 Gm. per 100 cc. On Nov. 12 it was noted that the patient had leukopenia and neutropenia and was febrile. He had received amobarbital (Amytal) and promazine, 250 mg. four times a day intermittently since Oct. 7, and meprobamate, 400 mg. intermittently. He received promazine, 200 mg. four times a day, from Oct. 15 to Nov. 12. A febrile toxic course followed, with pharyngeal ulceration, cervical adenitis with superficial ulceration, and severe sore throat with dysphagia. The lips and tongue were swollen, and the neck had the wooden-hard character of Ludwig's angina. His temperature ranged between 102.0 and 104.4 F (38.9 to 40.2 C). Treatment was with procaine penicillin, 600,000 units; streptomycin, 0.5 Gm., alternating with dihydrostreptomycin; benzathine penicillin G, 600,000 units by mouth; and oxytetracycline (Terramycin), 0.5 Gm. by mouth —all given every six hours.

Sternal aspirate on Nov. 12 was hypocellular, with no evidence of granulopoiesis and decreased numbers of erythropoietic elements and megakaryocytes.

Hemoglobin level was 10.8 Gm. per 100 cc. and hematocrit, 34%. The leukocyte count was 950 per cubic millimeter, with Türk's irritation cells and no neutrophils. The spleen was palpable, and there was a positive urine test for porphobilinogen (negative in a 1:10 dilution). This test was positive on Oct. 29, Oct. 30, and Nov. 1 but was not positive again on repeat determinations, including those at the time of test doses. On Nov. 15 the bone marrow was hypocellular, with normal erythropoiesis and thrombopoiesis. On Nov. 19 the bone marrow was more cellular, with progranulocytes and myelocytes, and the erythroid-myeloid ratio was 1:1. On Nov. 21 there was the first indication of granulopoietic response; leukocytes were 2,700 per cubic millimeter and the temperature abruptly became normal. On Nov. 22, the sternal marrow aspirate was very hypercellular, with increase in granulopoiesis. The leukocyte count continued to rise to a peak of 35,000 per cubic millimeter on Nov. 26, with 10% myelocytes, 22% metamyelocytes, and 29% nonsegmented and 25% mature neutrophils; increased platelets; and 1.5 to 2% reticulocytes. The hematocrit was 42%. Serum protein values and liver function test results were all normal.

Table 2.—*Observations in Two Cases at Onset of Therapy, During Agranulocytosis and Recovery, and During Drug Readministration*

	Onset of Therapy	After Stopping Therapy				During Drug Readministration

Dose, Gm.	Daily 0.8	Total 23.2	0	0		0.025	0.050	0	0.3

During the toxic course, the ulcerating lesions did not show evidence of pus formation but cleared up promptly after Nov. 21. The spleen regressed. The patient was later given a week's course of meprobamate, 400 mg. daily, without reaction and was given test doses of promazine without significant reaction (table 2), except that after the 50-mg. test dose he developed a slight rash over his forehead. He received 25 mg. of promazine on Dec. 13 and 50 mg. on Dec. 16, with slight increase in temperature to 99.2 F (37.3 C) and no change in any blood value except for the fact that the percentage of eosinophils increased to 13. The patient was readmitted to the hospital in February, 1958, at which time he received further test doses of the drug without reaction (table 2).

Case 3.—A 49-year-old male was admitted to the Neuropsychiatric Institute on May 25, 1957, because of a diagnosis of schizophrenic reaction. Two years previously he had had an episode of jaundice after chlorpromazine therapy. The leukocyte count was 5,700 per cubic millimeter and the hemoglobin level, 14.9 Gm. per 100 cc. Promazine, 50 mg. four times a day, was administered on admission and the dosage was increased gradually to 250 mg. four times a day. A total of 10.3 Gm. of promazine was given over a period of 18 days. Other drugs given included methylphenidate (Ritalin), digitalis, and mercaptomerin (Thiomerin). The patient was transferred to the medical service on the 18th hospital day with a tentative diagnosis of impending thyroid storm, temperature of 102 F, and tachycardia.

At the time of transfer, there were 1,300 leukocytes per cubic millimeter, without neutrophils. Sternal marrow aspiration revealed normal megakaryocytes, no evidence of granulopoiesis, normoblastic erythropoiesis, and numerous plasmacytes. Use of promazine was discontinued, and antibiotic therapy with penicillin, streptomycin, nystatin (Mycostatin), and novobiocin was instituted. Hydrocortisone therapy was started on June 18 in a dosage of 200 mg. per day. The patient remained febrile (temperature from 99 to 105.6 F [37.2 to 40.8 C]) until June 23, when his temperature became normal. During this acute episode he became jaundiced. The total bilirubin level reached a peak of 11.2 mg. per 100 cc. (5.6 mg. direct) on June 18, 1957, and cleared rapidly thereafter. The leukocyte count on June 25 was 22,600 per cubic millimeter, with 82% granulocytes, including immature forms. Repeat marrow aspiration, done on June 26, showed a striking increase in granulocytic elements, with an erythroid-myeloid ratio of 1:9, all stages of granulocytic development, and a relative increase in myelocytes. The subsequent course of this patient was complicated by the development of an abscess of the forearm and of empyema with bronchopleural fistula. Coagulase-positive hemolytic Staphylococcus aureus was cultured from both of these infectious processes. The infections cleared after surgical drainage. The hemoglobin level on Sept. 6 was 10.3 Gm. per 100 cc., and leukocytes were 5,000 per cubic millimeter.

Comment

The mechanism of agranulocytosis produced by phenothiazine-derivative drugs appears to follow a definite pattern. In a patient[6] who had developed a reaction to chlorpromazine, the drug was readministered at 10-mg. and 25-mg. doses without effect, and the blood reaction was then reproduced after 1.3 Gm. given over a 13-day period. Small doses will not reproduce a reaction.[7] Table 2 demonstrates the course of the agranulocytosis in two of our patients and negative results by readministration of small amounts of the drug. This is not the type of result which one would expect if a highly sensitive immunological mechanism were responsible, as is the case with reactions to aminopyrine. Attempts have been made to demonstrate leukoagglutinins in phenothiazine agranulocytosis[8] without success. In case 2, leukoagglutinins were sought by adding the patient's serum taken during the height of the agranulocytic action to normal leukocytes in the presence of a small amount of promazine. No leukoagglutination over that of the mixture of normal serum and normal leukocytes could be demonstrated. It would appear that this type of reaction is a drug idiosyncrasy or cumulative toxicity in which large doses of the drug given consecutively over a period of days produce bone marrow depression which is initially manifested in the granulocytic series. This reaction can be reproduced in the same person by giving a comparable dose of the drug again. It may be that agranulocytosis would recur if phenothiazine derivatives were given to a person who had developed a reaction after administration of one of these compounds. These drugs should probably be classified as agents occasionally associated with the occurrence of granulocytopenia, as suggested by Wintrobe and Cartwright.[9] It is interesting to note that jaundice and agranulocytosis do not very often appear concurrently.

The efficacy of steroid therapy in this form of agranulocytosis is debatable. The usefulness of corticotropin and cortisone in some blood disorders, especially those associated with continuing immune reactions, is well recognized.[10] However, the beneficial effects of these hormones in drug-induced agranulocytosis appear not to be well established. Adrenal cortex stimulation induces eosinopenia and neutrophil leukocytosis and evidence of erythrocytic proliferations. This is not constant or prolonged, except for the eosinopenia; the values revert to normal after use of adrenal cortical hormones is stopped.[11] A review of case reports suggesting beneficial effects of steroid therapy reveals that, after the recognition of the leukopenia and stopping of the use of the drug, evidence of bone marrow response appeared after 7 to 10 days, which is the same time range as that for those patients who did not receive steroids. The same pattern has been noted in case reports of agranulocytic reactions to drugs other than phenothiazine derivatives. The question has been raised[12] as to whether corticosteroid therapy is indicated. It may be argued that adequate antibiotic coverage and supportive care during a period of agranulocytosis should be sufficient therapy and that the administration of steroids might suppress a much needed immune response. The tabulation in table 1 of deaths due to agranulocytosis after the use of phenothiazine derivatives affords no argument either for or against the use of steroids. Experimental observations would indicate that steroids do not have a beneficial effect on the bone marrow after myeloid depression. It was noted in animals that after irradiation[13] the administration of cortisone had an adverse effect on bone marrow regeneration. It has been reported[14] that the leukopenia induced by nitrogen mustard administration can be increased by cortisone.

Splenomegaly was noted in case 2 and in several of the cases previously reported. The enlargement occurred during the period of agranulocytosis and disappeared on recovery. Splenomegaly may represent a reticuloendothelial and lymphoid reactive hyperplasia during the period of agranulocytosis.

Summary and Conclusions

The phenothiazine derivatives in general use at the present time include chlorpromazine, promazine, mepazine, promethazine, prochlorperazine, perphenazine, triflupromazine, thiopropazate, and trimeprazine. Agranulocytosis appears to be a definitely established reaction to chlorpromazine and promazine, and there are indications that other phenothiazine derivatives may have this potential action.

Most of the reactions appear to occur within the first 15 weeks of consecutive administration. If the agranulocytosis is recognized promptly, patients recover completely, usually about 10 days after use of the drug is stopped. Antibiotics, but probably not corticosteroids, should be administered.

The reaction appears to be an individual idiosyncrasy to a cumulative toxic dose of the drug. Cross sensitivity to other phenothiazine derivatives appears to be likely in the case of persons who have had agranulocytosis after the administration of one of these compounds. Readministration of small test doses does not result in a reaction, and leukoagglutinins have not been demonstrated.

Awareness and recognition of this drug reaction and familiarity with the various phenothiazine derivatives should prevent fatal reactions from developing in the future. Recovery appears to be complete and without residual bone marrow abnormality.

Dr. R. C. Bishop, University of Michigan Medical Center, provided the data and observations in case 3.

CLINICAL NOTES

SULFHEMOGLOBINEMIA DUE TO ACETOPHENETIDIN

Herbert Polesky, M.D., Harry J. Sacks, M.D.
and
M. C. Thorner, M.D., Los Angeles

The observation of cyanosis in a patient without findings of respiratory or cardiovascular disease or polycythemia vera leads one to consider as its cause the presence of an altered hemoglobin.[1] Although 5.0 Gm. of reduced hemoglobin is usually necessary to produce cyanosis, only 1.5 Gm. of methemoglobin or 0.5 Gm. of sulfmethemoglobin will cause detectable cyanosis.[2]

Once sulfhemoglobinemia or methemoglobinemia is suspected, spectrometric examination of the blood will confirm this diagnosis. However, at this point the sometimes difficult task of finding the offending agent begins, for numerous drugs have been incriminated, the most common of which are nitrates, sulfonamides, and aniline derivatives.[3] The following case history is illustrative of this problem.

Report of a Case

A 37-year-old woman, an interior decorator, was admitted to the hospital for the third time with a complaint of recurrent spells of weakness. For the past several years she had had spells of weakness which recently became more pronounced and were associated with increasing fatigue and lethargy. A few months prior to this admission she had completed a full-term pregnancy complicated only by low back pain. During the two months preceding her hospitalization, she had recurrent nonspecific low back pain. For relief she took up to 10 tablets daily of Daprisal and about 10 tablets daily of either Empirin compound or Bufferin. No history of ingestion of any other drugs was elicited. She was not exposed to heavy metals, other than paints. The family history and her own history were noncontributory. Review of systems revealed no cardiorespiratory or gastrointestinal symptoms.

From the Division of Laboratories (Drs. Polesky and Sacks) and the Department of Medicine (Dr. Thorner), Cedars of Lebanon Hospital.

Examination revealed an extremely lethargic, well-developed, well-nourished young woman. Her skin, lips, and nailbeds were a peculiar ashen-gray color. Her pulse rate was 66 per minute, respirations 20 per minute, blood pressure 110/60 mm. Hg, and temperature 98.6 F (37 C). The chest was clear. There was no cardiac enlargement or murmurs. The liver and spleen were not palpable. Edema was absent. Reflexes were equal and active, and no sensory loss or muscle weakness was detected. Psychiatric evaluation revealed a subsiding reactive depression.

Laboratory findings showed a hemoglobin level of 12.3 Gm.%; hematocrit value 39%; mean corpuscular hemoglobin concentration 32%; white blood cell count 6,250 per cubic millimeter, with 75% neutrophils (74% polymorphonuclear cells, 1% stab forms), 23% lymphocytes, 2% monocytes; platelets adequate; red blood cell morphology unremarkable; sulfmethemoglobin 0.8 Gm.%; methemoglobin absent. Results of urinalysis were negative; urine coproporphyrin, trace, and no uroporphyrin or porphobilinogen. X-rays of the chest, skull, and wrists were not remarkable. An electrocardiogram showed inverted T waves in leads aVR and aVL and V_1, a deep Q wave in aVL, and a low R wave in V_1 to V_6.

The patient's course was uneventful and afebrile. All drug therapy was stopped. Five cubic centimeters of 1% methylene blue given intravenously had no effect on the cyanosis. Her depression lifted, and she was discharged with decreasing cyanosis. In six weeks the cyanosis had disappeared completely.

Comment

The identification of the altered hemoglobin level is relatively easy and is of importance in deciding the form of therapy to be undertaken.[4] The level of sulfmethemoglobin (0.8 Gm.%) was found by analysis to exceed the minimum level (0.5 Gm.%) necessary for the production of cyanosis.

Although the exact chemical nature of sulfmethemoglobin is unknown, it is thought that an atom of sulfur is introduced into the hemoglobin molecule and that there is a change in the globin linkage with heme.[5] This compound has a characteristic absorption band at 618μ. Methemoglobin has a band at 630μ. Sulfmethemoglobin has a brownish color which, unlike the brownish color of methemoglobin, does not become red on standing or after bubbling oxygen through it. Further, the absorption band of methemoglobin disappears after the addition of a few drops of 5% potassium cyanide to the solution.[2]

It is felt that the etiological agent responsible for the ashen-gray cyanosis in this case was the acetophenetidin present in the drugs that the patient had ingested for relief of her "arthritic pains." Daprisal contains 0.16 Gm. of acetophenetidin, 0.16 Gm. of acetylsalicylic acid, 0.032 Gm. of amobarbital, and 0.005 Gm. of dextro amphetamine sulfate; Empirin compound contains 0.16 Gm. of acetophenetidin, 0.23 Gm. of acetylsalicylic acid, and 0.03 Gm. of caffeine; and Bufferin contains 0.325 Gm. of acetylsalicylic acid, 0.05 Gm. of aluminum glycinate, and 0.10 Gm. of magnesium carbonate but no acetophenetidin. This patient had a daily intake of up to 3.2 Gm. of acetophenetidin over a two-month period, or a total intake of about 192 Gm. of acetophenetidin.

In previous reports the acetanilid in Bromo-seltzer and other preparations was the etiological agent most commonly incriminated.[6] In 11 cases in the recent literature, the acetophenetidin contained in proprietary drugs has been implicated as the cause of sulfhemoglobinemia.[7]

Both acetophenetidin and acetanilid have similar metabolic pathways.[3a] When given with sulfur, these drugs produce sulfhemoglobinemia in rabbits and dogs.[8] Frequently, in cases of cyanosis secondary to sulfhemoglobinemia, the patients are constipated, and it is postulated that a source of sulfur from the intestine is partially responsible. The rare case of enterogenous sulfhemoglobinemia is thought to be caused by such a mechanism. In our patient there was no constipation, nor were sulfur-containing drugs being administered.

The presence of anemia in patients with sulfhemoglobinemia is inconstant.[9] In most of the previously reported cases, anemia was not a feature or, if present, was secondary to some other factor. Careful studies have shown that once sulfmethemoglobin is in a cell it remains there for the life of that cell. The life span of these cells is normal.[8] Neither methemoglobin nor sulfmethemoglobin is a toxic substance; they produce toxic symptoms by causing anoxia that results from the reduced oxygen capacity of hemoglobin so altered.[2]

While intravenously given methylene blue abolishes acquired methemoglobinemia, there is no satisfactory therapy for sulfhemoglobinemia except withdrawal of the offending drug.

Summary

A case of sulfhemoglobinemia with cyanosis was caused by acetophenetidin. Physicians should be alerted to the dangers of this agent, which is present in many proprietary drugs used by the general public and the profession.

HYPOKALEMIC MUSCLE PARALYSIS ASSOCIATED WITH ADMINISTRATION OF CHLOROTHIAZIDE

Theodore Cohen, M.D., Forest Hills, N. Y.

Chlorothiazide is a new orally given diuretic whose potency equals that of the parenterally given mercurial diuretics.[1] While in vitro it appears to be a carbonic anhydrase inhibitor, the latter effect is not strikingly evident in vivo.[2] It acts directly on the renal tubules [3] in a manner similar to that of the mercurial diuretics.[4] The result is an increased excretion of sodium, potassium, and chloride in the urine, accompanied by diuresis.

The side-effects do not appear to be troublesome.[5] Among those reported are (1) gastrointestinal disturbances, including nausea, vomiting, abdominal cramps, and epigastric distress; (2) hemorrhagic manifestations in which patients exhibited hematuria and petechiae without changes in the clotting mechanism; and (3) an exaggeration of epilepsy due to systemic alkalosis.[5a] Wilkins [5b] has reported sexual impotence as a complication of chlorothiazide therapy and Drerup and co-workers [6] treated a patient who developed jaundice with pathological evidence of bile stasis while receiving the medicament. Transient skin rashes have also been reported,[3] as have hyperglycemia and glycosuria.[1] A clinical picture of impending hepatic coma [7] and ammonia intoxication [8] in patients with liver disease who were treated with chlorothiazide has also been observed.

Hypokalemia is the most important side-effect.[9] It is noted in 40% of patients receiving chlorothiazide without supplemental potassium.[1] In half of these cases the serum potassium level falls below 3.5 mEq. per liter [5b] and may be accompanied by weakness and trembling. Caution has been urged in the use of chlorothiazide in patients with renal [5c] and cardiac disease.[10] Lowering of the serum potassium level predisposes patients with heart disease to cardiac arrhythmias and digitalis toxicity.[5c] This is particularly liable to occur if such patients are placed on a low-sodium diet, for in this situation there is an increased excretion of potassium by the kidney due to the unavailability of sodium.

A patient who was recently treated with chlorothiazide developed a marked hypokalemia accompanied by selective muscle paralysis. The latter responded dramatically to the administration of potassium. Dr. Gibson, director of medical research of Merck Sharp & Dohme, stated that according to the information available to him this case is the first instance in which the serum potassium level had dropped so low and muscle paralysis occurred while chlorothiazide was being administered.[11] The uniqueness of this case merits its publication.

Report of a Case

A 60-year-old man was referred for medical evaluation because his ophthalmologist told him that there were "signs of high blood pressure in the eyes." When first seen on Dec. 4, 1958, he had no other complaints. His history was noncontributory, including no personal or familial episodes of periodic paralysis. Findings of the initial physical examination were within normal limits except for overweight (height 5 ft. 7 in. [170.2 cm.], weight 201 lb. [91.2 kg.]) and hypertension (blood pressure 180/124 mm. Hg). Funduscopic examination revealed some arteriolar constriction. Hemoglobin concentration was 12.5 Gm.%. Urinalysis revealed a specific gravity of 1.010; no albumin or sugar was present; and microscopic examination showed an occasional red blood cell and white blood cell per high-power field. Therapy at that time consisted of a 1,200 calorie diet and 250 mg. of chlorothiazide to be taken twice daily. The patient was instructed to return in two weeks.

On Dec. 19 when he was seen again he stated that he felt well but that he had not followed the diet. His weight at that time was 212 lb. (96.1 kg.)

Assistant in Medicine, University Hospital; Instructor in Clinical Medicine, New York University Postgraduate Medical School, New York.

and blood pressure 190/80 mm. Hg. The patient was again advised about the necessity of following a low-calorie diet, and because the systolic pressure was still moderately elevated the chlorothiazide dosage was increased to 500 mg. twice daily.

During two subsequent visits on Dec. 29, 1958, and Feb. 6, 1959, his weights were 205 and 206 lb. (93.0 and 93.4 kg.). The blood pressure recordings were 170/95 and 165/90 mm. Hg. He felt well and stated that following the diet consisted in avoiding starchy foods. The chlorothiazide therapy was continued and dextro amphetamine was added at the last visit to aid him in curbing his appetite.

On March 2 he was seen at home because for the past two days he had been unable to bend his left thigh and raise his right arm. He added that one week prior to the onset of these symptoms he had noted a similar weakness in his right lower extremity. This lasted for two days and then cleared spontaneously. He had continued to take the chlorothiazide up to the time of examination. Physical examination revealed a complete inability on the part of the patient to flex his left thigh and to abduct his right arm. There were no sensory disturbances and the reflexes were normal. No pathological reflexes could be elicited and there was no weakness of any other muscle group. There was no elevation of the temperature or nuchal rigidity.

Serum Electrolyte Studies and Potassium Chloride Administration

	March											April

Potassium chloride administration		40 mEq. I.V. + 2 Gm. orally		2 Gm. q.i.d.	2 Gm. q.i.d.	2 Gm. t.i.d.	2 Gm. t.i.d.	2 Gm. t.i.d.	2 Gm. t.i.d.			

* Muscle paralysis no longer present.
† Before I.V. administration of potassium chloride.
‡ After I.V. administration of potassium chloride.

The patient was immediately hospitalized at University Hospital, where results of an initial complete blood cell count and urinalysis were essentially normal. A spinal tap done on admission (with difficulty) revealed an initial pressure of 270 mm. H_2O. The fluid was clear and contained nine white blood cells per cubic millimeter. Result of the Pandy test was slightly positive, and that of the Kolmer test was negative. Results of trichinosis complement-fixation and flocculation tests of the serum were negative. Neutralization studies on stool and cerebrospinal fluid specimens were negative for poliomyelitis, Coxsackie, and enteric cytopathogenic human orphan (ECHO) viruses.

Serum potassium level determined on the day of admission was 1.65 mEq. per liter. Because of the exceptionally low level the determination was repeated the following day and an identical result was obtained. It was then felt that the hypokalemia was secondary to the administration of chlorothiazide and was also responsible for the patient's symptoms. An electrocardiogram done at that time showed widening of the QRS complex with depressed S-T segments, and widened, inverted T waves fusing with prominent, upright U waves—all compatible with hypokalemia. On March 3 an intravenous infusion of 40 mEq. of potassium chloride was given, and immediately afterward the serum potassium level was 2.15 mEq. per liter. At this time the patient stated that the involved extremities felt somewhat stronger. However, a clinical examination failed to demonstrate any change. The patient was given 2 Gm. of potassium chloride by mouth that evening. The next morning the serum potassium level was 2.8 mEq. per liter and his general condition was unchanged. He was then started on therapy with potassium chloride, 2 Gm. four times daily. The morning of March 5 he awoke with full use of the affected extremities. His serum potassium level at that time was 2.95 mEq. per liter. The next day the potassium chloride dosage was reduced to 6 Gm. daily and was continued until March 10.

On March 5 the patient's serum sodium level was found to be elevated (see table) on successive determinations. Because of the possibility that aldosteronism might be present the salivary potassium level, which is characteristically elevated in this condition,[12] was determined on March 10 and found to be 21 mEq. per liter, which appeared to be within normal limits.[13] These tests, subsequent electrolyte studies, and the lack of resistance to therapy ruled out the diagnosis of aldosteronism. The patient was discharged from the hospital on March 11, feeling perfectly well. He was seen in April, at which time there was no evidence of recurrence of muscle paralysis, and his serum electrolyte levels were normal.

Summary and Conclusions

A patient developed muscle paralysis subsequent to hypokalemia during the administration of chlorothiazide. The marked drop in the serum potassium level and the clinical symptomatology were unusual; this appears to be the first such case reported.

The elevation of the serum sodium level accompanying this marked decrease in serum potassium is a change similar to that seen in aldosteronism. Perhaps, as has been previously suggested,[1] chlorothiazide in some way exerts its pharmacological action through the activation of aldosterone.

HEPATIC DAMAGE DURING CHLORPROPAMIDE THERAPY

George Brown, M.D., John Zoidis, M.D.
and
Maxwell Spring, M.D., New York

Recently a new arylsulfonylurea, chlorpropamide (Diabinese), has been released for the management of diabetes mellitus. Its mode of action is similar to that of other sulfonylureas, but it has a more potent hypoglycemic effect than tolbutamide and is excreted more slowly. As a result, lower dosages may be used and a fairly constant blood level obtained. Studies of acute and chronic conditions in animals have shown that this drug possesses a low order of toxicity.[1] Clinical trial in approximately 2,000 cases, for periods up to one year, indicates that in some patients hepatic function tests may show transient deviations from the normal. In general these abnormalities have not been indicative of serious hepatic dysfunction and have reverted to normal even when the drug therapy was not discontinued. In eight cases jaundice appeared, sometimes associated with a skin rash and eosinophilia. These cases have all occurred within two to five weeks of beginning therapy and have been characterized by an elevation of the alkaline phosphatase level and by the presence of intracanalicular biliary stasis. When chlorpropamide therapy was discontinued, the jaundice disappeared and the liver reverted to normal.[1a] It is the purpose of this communication to report three additional cases of liver injury which occurred in a series of 49 patients treated with chlorpropamide in a clinical trial of the drug at the diabetes clinic of the Bronx Hospital.

Report of Cases

CASE 1.—A 50-year-old woman had been known to have diabetes for 20 years. Her condition had been managed by diet and administration of 100 units of globin zinc insulin daily. In an effort to improve the degree and stability of her control, she was given in addition 1 Gm. of chlorpropamide per day. About three weeks later, she noted sensations of chill, weakness, and loss of appetite, followed in a few days by the discovery of dark urine, light stools, and rash on her trunk. With the passage of an additional week, by which time she had ingested a total of 27 Gm. of chlorpropamide, she noted jaundice. There was no pain, fever, nausea, or vomiting. Her history was negative for liver

---

From the Diabetes Clinic and the Department of Medicine of the Bronx Hospital.

or biliary tract disease. Her alkaline phosphatase level, which had been 10 King-Armstrong units before the drug therapy was started and 11 King-Armstrong units after two weeks of therapy, was found to be 37 King-Armstrong units. The white blood cell count was 6,300 per cubic millimeter, with a differential of 59% segmented forms, 30% lymphocytes, 2% monocytes, and 9% eosinophils. She was hospitalized on Oct. 10, 1958, for further studies.

The findings of the physical examination were negative, except for the presence of jaundice, a diffuse macular eruption on the trunk, and a soft, tender liver edge 2 fingerbreadths below the costal margin. Laboratory data on admission included the following findings: the alkaline phosphatase level was 80 King-Armstrong units, the serum bilirubin level 8.9 mg.%, and the cholesterol level 630 mg.%, with 34% esters. The thymol turbidity was 1.6 units and the cephalin flocculation test negative. The hemoglobin level was 11.6 Gm.%, and the white blood cell count 7,600 per cubic millimeter, with 74% segmented forms, 20% lymphocytes, and 6% eosinophils. Platelets numbered 490,000 per cubic millimeter. Results of urinalysis were negative, except for the presence of bile. On Oct. 16, the serum bilirubin level reached a peak of 9.4 mg.%, the alkaline phosphatase level was 86 King-Armstrong units, and the serum cholesterol level 770 mg.%. By the time of the patient's discharge these values had fallen to a serum bilirubin level of 0.8 mg.%, an alkaline phosphatase level of 26 King-Armstrong units, and a serum cholesterol level of 262 mg.%, with 75% esters respectively. The cephalin flocculation and thymol turbidity remained normal. On two occasions the serum albumin level was 4.1 and 4.0 Gm.%, respectively, and that of serum globulin 2.6 and 2.3 Gm.% respectively. A needle biopsy of the liver, performed on Oct. 16, showed normal liver architecture. There was mild pigmentation of the Kupffer cells and slight capillary bile stasis. While a spotty inflammatory reaction in the portal tracts was noted, no inflammatory or degenerative changes were observed in the hepatic cells. A gallbladder series performed on Nov. 10 showed several negative shadows suggestive of gallstones. The patient remained afebrile throughout her hospital stay. The rash and eosinophilia cleared by the fifth hospital day. Her diabetes was controlled by means of a diet containing 150 Gm. of carbohydrates, 75 Gm. of proteins, and 80 Gm. of fats, and the administration of 80 units of NPH insulin daily. She was discharged on Nov. 14, 1958, and was still asymptomatic when seen for a follow-up examination in January, 1959.

Case 2.—A 67-year-old woman was referred on Nov. 5, 1958, for admission from the diabetes clinic of the Bronx Hospital because of a rise of her alkaline phosphatase level from 13 to 53 King-Armstrong units while on chlorpropamide therapy. The patient had been a known diabetic for one year and had not followed a prescribed diet or taken insulin. Six weeks prior to her admission to the diabetes clinic, on Sept. 26, she appeared at the outpatient department of the Bronx Hospital complaining of marked polyuria and polydipsia, with weakness. On that day therapy with chlorpropamide, 1 Gm. per day, was started, and she was placed on a 1,500-calorie diet. The alkaline phosphatase level, which was 13 King-Armstrong units on Oct. 15 (three weeks after the onset of treatment), rose to 53 King-Armstrong units on Oct. 29 (five weeks after the onset of treatment). She experienced no pain, nausea, or anorexia. Her history was negative for liver or biliary tract disease. Medication was discontinued on Oct. 29, after a total of 32 Gm. of chlorpropamide had been taken.

At the time of admission, Nov. 5, 1958, she appeared asymptomatic, afebrile, and comfortable. There was no jaundice. The only significant finding was a soft, nontender liver, palpable 1 fingerbreadth below the costal margin. The remainder of the findings of the physical examination were normal.

The patient was put on a 1,500-calorie diet without insulin therapy. On admission the hemoglobin level was 79% (Sahli method) or 11.4 Gm.%; the red blood cell count was 4,200,000 per cubic millimeter; the total leukocyte count was 9,000 per cubic millimeter, with a differential of 1% eosinophils, 61% segmented forms, 37% lymphocytes, and 1% monocytes; and platelets numbered 215,000 per cubic millimeter. A sulfobromophthalein test on Nov. 5 showed 14% retention at the end of 45 minutes. The prothrombin time was 88% of control on the same day. On Nov. 6, the second hospital day, the blood glucose level was 153 mg.%, the van den Bergh reaction negative, the serum bilirubin level 0.2 mg.%, and the urea nitrogen level 14 mg.%. The total serum protein level was 6.7 Gm.%, with an albumin level of 4.5 Gm.% and a globulin level of 2.2 Gm.%. The alkaline phosphatase level was 22 King-Armstrong units. The total cholesterol level was 304 mg.%, with 72 mg.% of the total as esters. The prothrombin time was 42% of control (Smith's method). The thymol turbidity was 0.7 units and cephalin flocculation was negative at the end of 24 and 48 hours respectively. The urine did not contain bile. A needle liver biopsy performed on Nov. 11 showed no abnormality of architecture. A fair number of hepatic cells showed hydropic nuclei and some showed hyperchromatic nuclei. The portal tracts were mildly infiltrated with round cells. There was no evidence of bile stasis. On Nov. 14 the alkaline phosphatase level was 18 King-Armstrong units, the serum bilirubin level 0.4 mg.%, and the sulfobromophthalein test showed 5% retention at the end of 45 minutes. A gallbladder series performed on Nov. 19 gave normal results. On Nov. 20, the alkaline phosphatase level was 15 King-Armstrong units, and the total cholesterol level was 211 mg.%. The patient remained asymptomatic throughout her hospital stay and was discharged on Nov. 25, 1958, with her condition well controlled by administration of 20 units of NPH insulin daily. At a follow-up examination in January, 1959, she was asymptomatic and appeared clinically well.

CASE 3.—A 57-year-old housewife had been known to have diabetes for nine years. The disease had been well controlled by diet and administration of NPH insulin 90 to 110 units daily. She was admitted to the Bronx Hospital on Nov. 10, 1958. On Oct. 10, one month prior to her admission, therapy with chlorpropamide, 0.5 Gm. per day, had been started, and the NPH insulin intake was reduced gradually to 70 units daily. On Oct. 25, two weeks after the onset of treatment, the patient noted malaise, vague abdominal pains, and epigastric discomfort. On Nov. 7, two weeks later and three days prior to admission, she noted a skin eruption, light stools, and dark urine. There was no pain, nausea, or vomiting, but mild anorexia was noted. Her history was negative for liver or biliary tract disease. She discontinued the chlorpropamide therapy, but continued to take 70 units of NPH insulin daily. The total amount of chlorpropamide taken was 12.5 Gm. On Nov. 10, jaundice appeared and she was hospitalized. Her alkaline phosphatase level, which had been 13 King-Armstrong units on Oct. 16, one week after the onset of treatment with chlorpropamide, had risen to 17 King-Armstrong units on Nov. 5.

Physical examination revealed a middle-aged, well-nourished, well-developed female, afebrile and in no distress. There was jaundice of the sclerae, skin, and mucus membranes. A soft, nontender liver was palpable 1 fingerbreadth under the costal margin, and a scanty macular pink rash was noted on the chest. The remainder of the findings of the physical examination were normal. The patient was kept on a diabetic diet of 1,500 calories and received 70 units of NPH insulin daily. No other medication was given. The blood chemistry on Nov. 11 revealed a glucose level of 211 mg.% and a urea nitrogen level of 16 mg.%. The prothrombin time was 100% of control (Smith's method). The erythrocyte sedimentation rate was 79 mm. at the end of one hour (Westergren). On the same day, the hemoglobin level was 78% (Sahli method) or 11.3 Gm.%, the total number of leukocytes 7,050 per cubic millimeter, with a differential count of 3% eosinophils, 53% segmented forms, 43% lymphocytes, and 1% monocytes. The results of urinalysis were negative, except for a trace of bile. Urobilinogen was present in a 1:1 dilution. On Nov. 14 the blood showed an alkaline phosphatase level of 78 King-Armstrong units, the van den Bergh reaction was direct, delayed, with a serum bilirubin level of 1.4 mg.%. The total serum protein level was 6.8 Gm.%, with the albumin level 4.1 Gm. and the globulin level 2.7 Gm. The total cholesterol level was 432 mg.%. Cephalin flocculation was negative in 24 and 48 hours, respectively, and thymol turbidity 1.5 units. The blood glucose level was 168 mg.%. By Nov. 14 the rash was no longer discernible and the jaundice barely perceptible. A needle liver biopsy performed on the second hospital day was reported as showing normal hepatic architecture, with intense infiltration of the portal tracts by acutely and chronically inflamed cells. Mild bile stasis was noted, as well as some vacuolization of a number of liver cells. On Nov. 18 the serum bilirubin level was 1.1 mg.% and the alkaline phosphatase level was 43 King-Armstrong units. The gallbladder series done on Nov. 19 showed no pathology. The patient signed out against advice on Nov. 20, 1958, and did not appear for a follow-up examination.

Comment

The benign course of the hepatic damage, the elevated alkaline phosphatase values, and the liver biopsies demonstrating bile stasis make the type of jaundice due to chlorpropamide therapy similar to that due to thorazine hydrochloride[2] or to methyl testosterone.[3] This variety of hepatic damage, which may or may not be accompanied by jaundice, is characterized by intracanalicular obstruction due to edema and cellular infiltration around the minute intrahepatic bile ducts. It is to be noted that the pathological findings revealed by liver biopsy may be minimal even with fairly high elevations of the levels of serum alkaline phosphatase or bilirubin. The latent period before the onset of jaundice (or rising alkaline phosphatase levels) and, in two of our cases, the prodromal symptoms and the accompanying rash and eosinophilia, suggest that hypersensitivity may be the mechanism involved. As in the case of thorazine hepatitis, this sensitivity apparently may disappear, since the drug therapy may be resumed at a later date without a recurrence of the untoward hepatic effects. This was not tried in any of our cases, but has been done many times with thorazine[4] and by Hamff and co-workers[5] with chlorpropamide without repetition of the jaundice.

In order to detect this type of reaction to chlorpropamide, the serum alkaline phosphatase level should be determined at weekly intervals at least during the first six weeks of its administration and use of the drug discontinued if the value rises above normal. In our experience to date, these cases have all occurred within one to six weeks after onset of therapy, and the jaundice is generally preceded by a rash. According to Shay and Siplet,[6] a rise in the level of serum alkaline phosphatase indicates hepatic sensitivity, which may be reversed by discontinuation of the drug therapy. Discontinuation of use of the drug was the only treatment employed in the cases presented. It is to be noted that the dosages employed in these cases, 0.5 to 1.0 Gm. daily, were larger than those currently being recommended by the manufacturer. Because of the slow excretion rate of chlorpropamide, initial dosage should be 0.25 to 0.5 Gm. daily. In occasional cases as little as 100 mg. daily can be used as a maintenance dosage.

Summary and Conclusions

Hepatic demage occurred in 3 out of 49 patients employed in a clinical trial of chlorpropamide (Diabinese) therapy. The jaundice which occurred in two of the three cases was demonstrated to be due to intracanalicular bile stasis. This could not be shown in the third case, where a sharp rise in the alkaline phosphatase level occurred without jaundice; but the elevation in the alkaline phosphatase level and the abnormal retention of sulfobromophthalein suggest that the same mechanism was operative. The pathology revealed by biopsy was minimal in all three cases and not as severe as the liver function abnormalities would have indicated. Complete recovery occurred in all. It is suggested that this reaction may occur more frequently when the dosage of chlorpropamide exceeds 0.5 Gm. daily. Its use should be monitored by periodic determinations of the alkaline phosphatase level for the first six weeks.

JAUNDICE OCCURRING DURING NICOTINIC ACID THERAPY FOR HYPERCHOLESTEREMIA

Arthur U. Rivin, M.D., Los Angeles

The administration of nicotinic acid in dosage of 3 to 6 Gm. a day has proved to be an effective method of reducing serum cholesterol levels. Experience with this medication for periods up to three years has been reported from the Mayo and the Jackson clinics.[1] Except for a few patients in whom there has been a transient abnormality of cephalin-cholesterol flocculation or transaminase, no renal, hematopoietic, or liver abnormalities have been noted.[2] Sulfobromophthalein (Bromsulphalein) tests and liver biopsies have failed to indicate other evidences of toxicity.[3] However, a definite decrease in glucose tolerance with some glycosuria has been noted.[4]

This report is submitted in order to record a case of jaundice occurring during the administration of nicotinic acid and presumably due to intrahepatic cholestasis resulting from drug toxicity.

Report of a Case

A 23-year-old man was first referred to me in June, 1957, because of an abnormal serum cholesterol level of which he had been aware since he was 17 years of age. He had no symptoms. His mother had died at 40 years of age of a myocardial infarction; his only brother, aged 20, is also known to have a cholesterol abnormality.

Pertinent features of the physical examination revealed a well-appearing, 6 ft. (182.88 cm.), 132 lb. (59.9 kg.) male with dense arcus senilis and xanthomas in the extensor tendons of the fingers, in the Achilles tendons, and in the plantar fascia. An electrocardiogram revealed normal findings. Three serum cholesterol measurements varied from 300 to 350 mg.%.

A 30-Gm. animal fat diet was established, with 3 oz. (85.05 Gm.) of supplemental corn oil administered daily. The patient was not seen again until

---

Assistant Clinical Professor of Medicine, Medical Center, University of California, Los Angeles.

October, 1957, at which time his cholesterol level was 373 mg.%. In December, 1957, the administration of nicotinic acid was begun, 1 Gm. three times a day after meals. The remainder of the events in his course, including the side-effects and the laboratory data, are depicted in the figure. It will be noted that there was a prompt decrease of the serum cholesterol level to 225 mg.%, and it was maintained at levels between 150 and 215 mg.% for 40 weeks. When the administration of nicotinic acid was discontinued because of severe itching, the serum cholesterol level quickly returned to more than 400 mg.% then fell sharply again with the reinstitution of nicotinic acid therapy. The decreasing size of one of the fascial xanthomas is depicted in the figure. During the 72nd week, when the patient was first noted to have jaundice and the medication was stopped, the only complaints were of itching and excessive sweating. His appetite and strength were normal and he was afebrile. The liver was palpable 4 cm. below the costal margin but was not tender. Laboratory studies disclosed bile-tinged urine with many granular and cellular casts, a few red blood cells, and no albumin. The complete blood count was normal. Liver function tests revealed a total serum bilirubin level of 7.4 mg.% with a one minute direct of 1 mg.%, alkaline phosphatase of 45 King-Armstrong units, thymol turbidity of 3.8 units, creatinine of 1.04 mg.%, fasting blood sugar level of 74 mg.%, and serum glutamic oxalacetic transaminase level of 91 units. Prothrombin time, reticulocyte count, serology, cephalin-cholesterol flocculation tests and heterophil agglutination time were normal. The patient was hospitalized. During a 20-day period the bilirubin, alkaline phosphatase, and transaminase levels and urinalysis returned to normal and the itching disappeared. The cholesterol also returned to pretreatment levels. No therapy was initiated other than rest and discontinuing the administration of nicotinic acid.

Comment

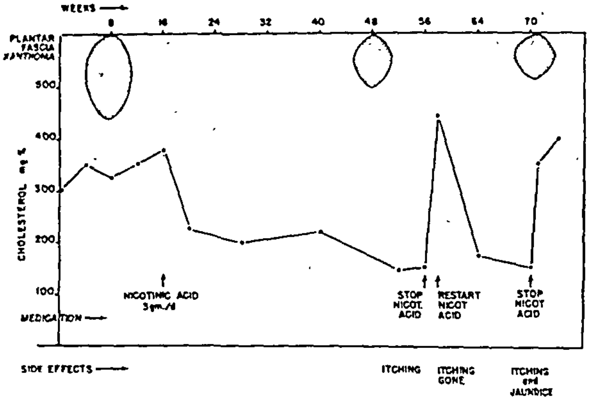
The rationale for the use of nicotinic acid and the physiological mechanisms for reducing serum cholesterol levels are only partially understood.[5] There is good reason to suspect, however, that there are alterations of the enzyme systems of the liver which are involved in cholesterol synthesis and conversion to bile acid.[6] It is conceivable that such alteration of liver activity could result in the kind of liver damage produced by methyl testosterone, chlorpromazine, and other drugs.[7]

Of the 18 other patients in our series currently taking nicotinic acid as a cholesterol depressing agent, no other serious toxic side-effects have been noted. One patient had transient glycosuria. In general there has been a gratifying decrease in serum cholesterol levels and relative concentration of beta-lipoprotein. Certainly in a disease such as familial hypercholesteremia, with its grave potential for early coronary disease, one is justified in using any relatively safe method to reduce serum cholesterol levels. Moreover, it may be possible to remove lipids from tissue deposits, since in this case there was demonstrable reduction in xanthoma size.

Summary

A patient with familial hypercholesteremia and tendon xanthomas exhibited marked reduction in serum cholesterol levels after therapy with large doses of nicotinic acid. The treatment was discontinued after 14 months because of the onset of jaundice, which probably represented intrahepatic cholestasis due to nicotinic acid toxicity.

Veterans Administration Center, Bldg. 114 (25).



Effect of nicotinic acid in large dosage on serum cholesterol levels.

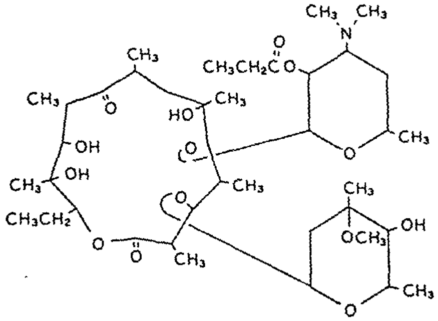
COUNCIL ON DRUGS

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based on available evidence and do not in any case imply endorsement by the Council.

H. D. Kautz, M.D., *Secretary.*

Erythromycin Propionate (Ilosone).—Propionyl erythromycin ester.—The propionic acid ester of erythromycin. The structural formula of erythromycin may be represented as follows:



Actions and Uses.—Erythromycin propionate is active against the same pathogenic organisms and has the same uses as erythromycin free base. When administered orally, this ester produces an earlier onset of therapeutic blood levels than does the free base. Blood levels are also higher and of longer duration than those attained with like amounts of the free base. (See the monograph on erythromycin in New and Nonofficial Drugs.)

Dosage.—Erythromycin propionate is administered orally. The usual dose for adults ranges from 250 to 500 mg. every six hours, depending on the severity of the infection. For overwhelming infections, doses as high as 1 Gm. every six hours have been used. In such cases, however, institution of parenteral therapy should be considered. For children up to 50 lb. (22.7 kg.) of body weight, the usual daily dose is 125 mg. every six hours. Heavier children may receive the full adult dose.

Preparations.—capsules 125 mg. and 250 mg.

Year of introduction: 1958.

Eli Lilly and Company cooperated by furnishing scientific data to aid in the evaluation of erythromycin propionate.

Relaxin (Cervilaxin, Releasin).—A factor which produces relaxation of the pubic symphysis and dilation of the uterine cervix in certain animal species. It is a protein or polypeptide of relatively low molecular weight extracted from the ovaries of pregnant sows. Relaxin is assayed biologically.

Actions and Uses.—Relaxin is a naturally occurring substance which is produced by the corpus luteum during pregnancy. Increasing concentrations of relaxin can be detected in the blood and urine of animals and humans during the last two-thirds of the gestation period; it virtually disappears within 24 hours after delivery. The physiological function of relaxin during pregnancy is not known. When given to castrated, estrogen-primed guinea pigs, the drug causes a relaxation of the pubic symphysis. This effect, due to proliferation of capillaries and dissolution of collagen fibers, forms the basis for one of its biological assays. Relaxin has also been demonstrated to inhibit, both in vivo and in vitro, the contractions of uterine muscle in experimental animals. There is some evidence that it effects a relaxing or softening of the uterine cervix of pregnant laboratory animals and humans at term. The relationships, both chemical and physiological, between relaxin and lututrin are far from clear. However, the recent application of countercurrent distribution and chromatographic techniques would suggest the presence in the ovary of at least two distinct factors possessing uterine relaxation activity. One of these factors, relaxin, in addition to this effect on the uterus, also is capable of exerting a pronounced relaxing effect on the pubic symphysis. Since this latter effect is minimal with the second factor, it is conventional to reserve the term "uterine relaxing factor" for lututrin.

The ability of relaxin to inhibit uterine contractions has been demonstrated both in vivo and in vitro in experimental animals and humans. This inhibition is apparently not related to the mechanism of oxytocin stimulation, since the latter will restore uterine contractions even in the presence of relaxin. Further, tokodynamometer studies in humans have revealed a similar effect on uterine motility. Such experiments led to the introduction of relaxin as an agent designed to halt premature uterine contractions between the 29th and 36th week of pregnancy. The multiplicity of factors causing premature labor, the difficulty of identifying true labor, the lack of properly controlled series, and differences in dosage or route of administration of relaxin have all contributed to equivocal results in this indication.

The principal therapeutic interest of relaxin in obstetrics lies in its effects on the uterine cervix. As a result of favorable animal experiments, the drug has been proposed for clinical use as a "cervical softening" agent which is said to shorten the duration of full-term labor by facilitating cervical dilation. Although many clinical investigators believe that relaxin exerts a cervical softening effect, there is some disagreement as to its merits in the shortening of labor. On the basis of subjective observations, some obstetricians report that relaxin is effective in easing and shortening labor in the majority of patients, primiparas or multiparas, provided that the cervix is already effaced and dilated at least 2 to 3 cm. at the time the drug is given. Conversely, other investigators, employing more objective clinical methods, have been unable to detect any effect. Part of the confusion in this regard arises as a result of the frequent use of relaxin in conjunction with oxytocic agents for the elective induction of labor at term. However, it would appear from recent controlled experiments that the responsiveness of the uterus to either endogenous or exogenous oxytocin may contribute materially to the effects of relaxin on the uterus. If labor contractions are well established and at frequent and uniform intervals, the administration of relaxin may shorten the course of labor. On the other hand, the administration of the drug to a patient having desultory labor frequently results in a temporary cessation or slowing of the progress of labor. It should be kept in mind that the cervical softening effect of relaxin is of little help in dysfunctional labor or uterine inertia in which the ineffectiveness or weakness of myometrial contractions, and not the degree of cervical dilation, is the factor responsible for the impeded progress of labor. Hence, there seems to be little rationale for the use of relaxin alone in the induction of labor, since oxytocin is necessary to establish good uterine contractions. Its suitability for use in cases of so-called cervical dystocia must await the results of double-blind studies now in progress.

Relaxin has been proposed for use in the treatment of severe dysmenorrhea. The rationale for its use in this indication is based first on tokodynamometer studies, which demonstrate strong uterus motility inhibiting properties in dysmenorrheic patients, and secondly on the cervical softening effect, which has been compared to mechanical dilation of the cervix prior to the onset of catamenial flow that frequently provides relief of pain. Controlled studies now in progress may shed more light on the usefulness of the drug for this purpose.

Among the miscellaneous proposed uses of relaxin is its employment to aid in the expulsion of retained dead fetus and the prevention of hypofibrinogenemia. In one series of cases, the use of large doses of relaxin for cervical softening prior to the use of oxytocin for induction of labor was claimed to be of significance. However, confirmation of this observation in a controlled series is indicated.

One of the experimentally observed effects of relaxin in laboratory animals has been an increase in the elasticity of the skin. Hence, the drug has been tried clinically for the treatment of scleroderma. Some improvement, as evidenced by relief of vasospasm, healing of trophic ulcers, and increase in skin elasticity, has been reported by several authors. Such symptomatic improvement continues as long as relaxin is administered, but the patients usually regress when therapy is terminated.

Since relaxin is a pork protein, it can give rise to sensitivity reactions ranging in severity from chills after its intravenous administration to acute anaphylactoid shock. Although the latter severe reaction has been encountered only rarely, skin testing is advisable for all patients. Except for occasional allergic manifestations, no other side-effects or untoward reactions have been reported.

Dosage.—Relaxin is administered intravenously or intramuscularly. The product is presently assayed by two methods, both of which equate dosage in terms of milligrams. One assay utilizes a guinea pig unit (G. P. U.) which is defined as "that amount of relaxin which produces relaxation of the pubic symphysis in two thirds of a group of 12 or more guinea pigs." The mouse assay is also utilized. This consists of the direct measurement of the interpubic ligament in estrogen-primed immature mice. Since the assay procedures are not precise and the technique of assay varies, the comparative potency of commercial preparations has not been clearly elucidated.

At the present time, precise recommendations for dosage are not possible. However, for cervical softening in normal labor or in cases of cervical dystocia, the proposed doses range from 40 to 120 mg., administered by intravenous drip in 250 to 500 cc. of sterile diluent at rates varying from 4 to 8 cc. per minute. Alternatively, the drug has been injected intramuscularly in doses of 40 mg. every two hours for three doses.

When used in conjunction with oxytocic agents for the elective induction of labor, the drug is administered by intravenous drip after rupture of the membranes. The dosage is that outlined previously for normal labor.

Although the clinical evidence to support its efficacy in premature labor is equivocal, relaxin has been administered intramuscularly in doses of 40 mg., followed by 20 mg. every two hours. It has also been given intravenously in doses of 40 to 80 mg., in 1,000 cc. of 5% dextrose in water for injection at a rate of 4 cc. per minute.

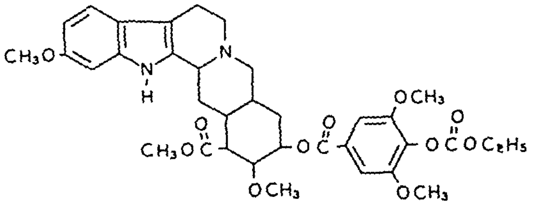
Proposed intramuscular doses for other claimed uses of relaxin are as follows: for dysmenorrhea, 20 mg. every four hours; for scleroderma, initially 20 mg. per day until therapeutic effects are known, followed by the lowest doses compatible with continued improvement; for delivery of retained dead fetus, 320 mg. in six doses over a period of 12 hours. Until more evidence of clinical efficacy appears in the literature, the foregoing proposed doses are considered experimental.

Preparations.—solution (injection) 20 mg. in 1 cc., 40 mg. in 2 cc.

Year of introduction: 1956.

The National Drug Company and Warner-Chilcott Laboratories, Division of Warner-Lambert Pharmaceutical Company, cooperated by furnishing scientific data to aid in the evaluation of relaxin.

Syrosingopine (Singoserp).—Carbethoxysyringoyl methyl reserpate.—Syrosingopine is prepared from reserpine by hydrolysis and reesterification. The structural formula of syrosingopine may be represented as follows:



Actions and Uses.—Syrosingopine is proposed for use as an antihypertensive agent and is closely related chemically to reserpine. (See the monograph on reserpine in New and Nonofficial Drugs.) When equal doses of the two drugs are compared, syrosingopine is both less potent and less toxic than reserpine. The two probably have about the same margin of safety.

Syrosingopine depresses the blood pressure in anesthetized and unanesthetized normotensive dogs, neurogenic hypertensive dogs, and in rats with adrenal regeneration hypertension. In dogs, the hypotensive effect is accompanied by a reduction in heart rate of 15 to 20%. It also reduces the rate of the isolated heart without altering the force of contraction or the coronary blood flow. It obtunds the carotid occlusion reflex.

Small doses of syrosingopine in dogs produce miosis, slight respiratory stimulation, and relaxation of the nictitating membrane. Larger doses produce sedation. It is one-twentieth as potent as reserpine in depressing the spontaneous activity of mice and one-tenth as potent in impairing the performance of monkeys in a discrimination learning task. Syrosingopine stimulates the secretion of hydrochloric acid in the denervated Heidenhain pouch of the dog but is less active in this respect than reserpine.

Clinically, syrosingopine alone is effective in some cases of mild or moderate labile hypertension. However, as is the case with all Rauwolfia compounds, syrosingopine generally will not provide satisfactory control of severe hypertension unless it is used in conjunction with more potent antihypertensive drugs. When given in combination with such agents, syrosingopine may make it possible to reduce their dosage.

Chronic toxicity studies in animals have disclosed no serious adverse effects on the bone marrow, liver, kidney, or other tissues. Side-effects reported in the clinical usage of the drug are similar to those of other Rauwolfia alkaloids. The most frequent of these is nasal congestion, followed closely in order of incidence by gastric complaints, drowsiness, and fatigue. Less frequently reported symptoms include headache, increased dreaming, emotional depression, and skin eruption.

To date, syrosingopine has been used only for the management of hypertension. Its advantages and limitations appear to be similar to those of other Rauwolfia drugs. Although early reports indicate that side-effects may be less troublesome than with other members of this group, a definitive assessment of the efficacy and toxicity of syrosingopine relative to the parent substance reserpine and other antihypertensive agents must await further clinical trial.

Dosage.—Syrosingopine is administered orally. The optimal dose (i. e., that which produces the best control of blood pressure without prohibitive side-effects) must be carefully determined for each patient. The suggested initial dose is 1 mg. per day. Since the effects of syrosingopine are manifested only slowly, it is advisable to maintain the initial dosage for a period of two weeks. Then, if there is inadequate clinical response, the daily dose may be gradually increased up to 3 mg. (in divided amounts), provided that each increase is maintained for a sufficient period to establish the level at which untoward effects appear. Occasionally, a patient may tolerate a higher daily dose.

Preparations.—tablets 1 mg.

Year of introduction: 1959.

Ciba Pharmaceutical Products, Inc., cooperated by furnishing scientific data to aid in the evaluation of syrosingopine.

REGRESSION OF DISEASES.—A communicable disease may spread throughout an area from one or more foci, and then gradually recede, even without effective treatment, until it is again confined to a few foci, or even disappears. Trachoma, for example, was brought into Europe by Napoleon's army on its return from Egypt, and ravaged the entire continent; but it has now practically disappeared from most European countries. Yaws has similarly almost disappeared from Ceylon, where in 1916-1920 there were 30,000 to 35,000 people with yaws lesions attending the outpatient departments of hospitals every year.—Yaws: Disease in Regression, *WHO Chronicle,* May, 1959.

COUNCIL ON FOODS AND NUTRITION

The Council has authorized publication of the following report.

Philip L. White, Sc.D., *Secretary.*

PROBLEM OF ANTIBIOTICS IN FOODS

Henry Welch, Ph.D., Washington, D. C.

In the United States antibiotics are probably our most important and most widely used therapeutic agents, and it is unlikely that any one of us will pass from "cradle to grave" without having one or more administered to us for some sound medical reason.

Background to the Problem

In 1957, total antibiotic production was over 2,500,000 lb., and it probably need not be emphasized here that these drugs have had wide and, in some cases, indiscriminate use. Their remarkable curative powers, more pronounced perhaps in the early days than now, resulted in their being injected, insufflated, given by mouth, spread on every part of the body, and sprayed intra-abdominally, intracisternally, intrapleurally, and intravaginally; no surface or cavity of the body has remained inviolate.

There are now over 400 preparations of antibiotics available for clinical use, and they run the gamut of injectables, ointments, powders, sprays, capsules, syrups, ear and eye drops, suppositories, troches, and tablets. Antibiotics have saved tens of thousands of lives in the past 15 years, and the reduction in the rates of mortality, morbidity, and complications of diseases has affected the lives of millions. Nevertheless, with such major advances in therapy and consequent wide use (not to mention indiscriminate use), unfortunately we have to face the accompanying untoward side-reactions that invariably follow. In the case of penicillin, a relatively atoxic drug, the "side-reaction" is its potentiality for sensitizing certain individuals. Although the other antibiotics are, in general, poor sensitizers, other side-reactions may occur after their administration. Thus, we have the initial provocation brought about by the extensive therapeutic and prophylactic use of a group of very valuable drugs.

Unfortunate Reactors

It is estimated that about 10% of the population in the United States has a tendency to become sensitive in the course of a lifetime to some food, drug, cosmetic, or other substance. Within this group of people there is a great variation in susceptibility to sensitization. Some acquire it easily, whereas others are more resistant. Some may be sensitive on first contact (the atopic group), while others require at least one contact, and still others may require several contacts before exhibiting a reaction. The reactions, too, vary in degree from mild, transient rashes to prolonged urticaria, and from a brief asthmatic attack to fatal anaphylactoid shock. Fortunately, these serious allergic manifestations occur less frequently in children to whom tons of antibiotics are administered yearly.

Since the population of the United States is estimated at over 175 million, we are concerned primarily with perhaps 17 to 20 million individuals who may react to contact with antibiotics—through proper therapeutic use or, inadvertently, through eating or drinking foods containing them. In the first case, the physician and patient have a choice, but in the latter instance there is none.

Introduction of Antibiotics in Foods

The extension of the uses of antibiotics to fields other than for prevention and treatment of human disease has magnified the problems of the physician from the standpoint of the side-reactions he may encounter in his daily practice.

Antibiotics are used in animal nutrition for promotion of growth in swine, chicks, and poults. Therapeutic and prophylactic use of large quantities of antibiotics is made for animals such as cows, beef cattle, swine, and chicks. These drugs are now being used as crop sprays to prevent blight in apples, pears, walnuts, and beans and to combat bacterial diseases of tobacco, tomatoes, peppers, and cherries. Two antibiotics, chlortetracycline and oxytetracycline, have been approved for use as preservatives on poultry and fish. A number of studies have been made to demonstrate their effectiveness as preservatives for vegetables, beef, ham, and other perishables.

The actual or potential introduction of antibiotics into the food supply poses the same problem as does the use of any other chemical. This grow-

---

Director of Division of Antibiotics, Food and Drug Administration, U. S. Department of Health, Education, and Welfare.

ing use of chemicals in food is one of the most serious problems facing public health authorities today, increasing the complexity of diagnosis and treatment immeasurably. It should be emphasized, however, that the problem of contamination of foods with antibiotics is very small when compared with other potential chemical contaminants of food. There is virtually no limit to the expanding list of chemicals that may find their way into our food supply. Chemicals are promoted as stabilizers, preservatives, disinfectants, antioxidants, extenders, tenderizers, emulsifiers, growth promoters, fumigants, herbicides, defoliants, fungicides, miticides, bleaches, sweeteners, conditioners, colors, and flavors. In addition, food packages that incorporate new plastics, enamels, films, plasticizers, catalysts, and coatings are further potential sources of food adulteration.

Uses of Antibiotics

Animal Feed.—Antibiotics are used in animal feed for growth stimulation and for the prevention and treatment of disease. The quantities of antibiotics authorized by the Food and Drug Administration in such feeds range from 5 to 200 ppm. When these medicated feeds are used in the manner prescribed by the FDA, there are no drug residues in the meat, eggs, or milk of treated animals. Therefore, when such feeds are properly used, they do not constitute a public health hazard. However, there is always the possibility of misuse.

Crop Sprays.—Antibiotics used as crop sprays are dissipated before the edible portion of the plant is formed, and, since they do not reach the consumer, no public health problem is involved.

Food Preservation.—Extensive experiments have been conducted to explore the potentialities of antibiotics as food preservatives. In November, 1955, the FDA approved the use of chlortetracycline for the preservation of raw poultry. Approximately one year later similar approval was given for oxytetracycline. Tolerance levels for these drugs were established under the provisions of the Miller Pesticide Chemicals amendment to the federal Food, Drug, and Cosmetic Act, passed by the 83rd Congress in 1954. These drugs act as preservatives and extend the "shelf life" of the fowl. Under the Miller amendment, the applicant must demonstrate "usefulness" to the satisfaction of the United States Department of Agriculture and "safety" to the FDA.

The tolerance level in the raw bird for both chlortetracycline and oxytetracycline was established at 7 ppm in any part of the bird. (This is about 1.5 mg. per serving of a one-half pound.) However, before approval of this tolerance level was granted, it had to be shown that no antibiotic residues could be found in the poultry after cooking by broiling, frying, boiling, or baking. In April, 1959, a tolerance level of 5 ppm was established for chlortetracycline in certain kinds of raw fish and shellfish.

A considerable number of investigations of the usefulness of antibiotics in the preservation of meats also have been completed. However, approval of this use by the establishment of tolerance levels under the Miller amendment have not been granted as yet and can be obtained only when conclusive evidence is presented that such use is not detrimental to the health of the general public.

Indirect Antibiotic Adulteration of Milk

In addition to being directly introduced into the food supply, antibiotics also may find their way indirectly into foods. In 1948, it was noted that milk from cows treated for mastitis with penicillin by intramammary infusion often failed to produce a satisfactory cheese product. This was due to the inhibition of the starter culture used in cheese manufacture by the antibiotic present in the milk.

Realizing that antibiotics might also reach the consumer by way of milk, the FDA required that mastitis preparations carry a warning in their labeling to the effect that "milk from treated segments of udders should be discarded or used for purposes other than human consumption for at least 72 hours after the last treatment." In further recognition of the possibility that antibiotics might get into the food supply, a statement of policy was issued in February, 1953, by the Secretary of the U. S. Department of Health, Education, and Welfare concerning the direct or indirect addition of antibiotic drugs to foods for human consumption. In effect, the policy statement was as follows: "The presence of antibiotic drugs in foods intended for human consumption, or the direct or indirect addition of such drugs to such foods, may be deemed an adulteration within the meaning of section 402 of the Federal Food, Drug, and Cosmetic Act."

Very large amounts of antibiotics are used in the treatment of milk-producing cows infected with mastitis. It is estimated that more than 75 tons of these drugs is used yearly in the treatment of this widespread infection. The great bulk of infected cows are treated by udder infusion, for which purpose a variety of products are available. Penicillin is used in perhaps the greatest volume. However, other antibiotics, such as dihydrostreptomycin, streptomycin, the tetracyclines, neomycin, polymyxin, and bacitracin, as well as the sulfonamides, are used for treatment and prophylaxis. Experience has shown that the entire amount of infused antibiotic or sulfonamide is eliminated by regular milking over a period of three days. It appears that failure to observe the warning given in the labeling of mastitis preparations concerning the discarding of milk from treated cows is largely responsible for the antibiotic residues that may be present in the milk supply.

During the years 1954, 1955, and 1956, three surveys were made to determine the antibiotic content of fluid market milk. In these surveys, conducted by the FDA, U. S. Department of Health, Education, and Welfare, a total of 2,274 samples were examined. Every state in the United States was included in these investigations. An average of 6.9% of the samples examined contained penicillin in concentrations varying from 0.003 to 0.550 units per milliliter. Other dairy products tested, including powdered milk, evaporated milk, ice cream, butter, cheese, shell eggs, and broken eggs, were found to be free from antibiotic residues.

Recent Advances in Antibiotic Problem

About one year ago a medical advisory panel accepted the invitation of the Commissioner of the FDA to consider the public health problems involved by the presence of antibiotics in market milk. The members of the advisory panel were Drs. Wesley W. Spink, chairman, University of Minnesota; Harry F. Dowling, University of Illinois; Samuel M. Feinberg, Northwestern University; Chester S. Keefer, Evans Memorial Hospital, Boston; Perrin H. Long, State University of New York; Walsh McDermott, Cornell University Medical College; Robert Popper, Veterans Administration Hospital, Memphis, Tenn.; and Bernard B. Siegel, Jewish Hospital of Brooklyn. After an all-day session, during which the problems involved were discussed thoroughly, it was apparent that our main health problem was concerned with penicillin, even though the other antibiotics used in mastitis preparations were found in approximately 1% of the samples examined. It was the consensus of the panel that these antibiotics—the tetracyclines, streptomycin, dihydrostreptomycin, bacitracin, polymxin, and neomycin, which may be found in mastitis preparations, did not at that time pose a public health problem.

It was agreed that penicillin is a very active, antigenic substance and, even in the low concentrations found in milk, might well cause reactions in highly sensitive individuals. It was apparent that the physician should be most concerned in his practice with the latter persons who constitute something less than 10% of the population. It seemed certain that in these individuals reactions could occur. Such reactions could vary in intensity from mild transient ones to possibly serious ones, the serious reactions occurring in those individuals exquisitely sensitive to penicillin. Because scientific proof is essential, it was the consensus of the panel that further studies were necessary with highly sensitive human volunteers to determine whether the ingestion of milk containing those concentrations of penicillin now found in some market milk would cause allergic manifestations.

Recently, the FDA has taken three steps to alleviate the public health problem involved: 1. Through cooperation with the U. S. Department of Agriculture, an intensive program has been initiated to educate the farmer concerning the importance of discarding, or using for purposes other than human consumption, milk from cows treated for mastitis with antibiotic drugs for a period of three days following the last treatment. In addition, the National Milk Producers Federation, which includes some 500,000 farmers, is assisting in this educational program through their state agents. 2. On Jan. 23, 1957, a notice was published in the *Federal Register* concerning the warning statement that is required in the labeling of antibiotic drugs intended for intramammary infusion. It was proposed that for greater conspicuousness this warning be placed on the immediate container of the drug rather than in the literature accompanying it. This is now required. 3. On Feb. 9, 1957, a "Notice of Proposed Rule Making" was published in the *Federal Register,* limiting the penicillin content of mastitis preparations to 100,000 units per dose. This became effective on Aug. 12, 1957.

In the fall of 1958 and the winter of 1959, a fourth nationwide survey of milk was conducted by the FDA to determine if the program discussed above had reduced or eliminated antibiotics from our milk supply. A total of 1,170 samples of raw milk was collected from tank trucks after pickup from dairy farmers or directly from individual producers. Each sample was examined for residues of penicillin, streptomycin, the tetracyclines, bacitracin, polymyxin, and neomycin, all of which are used in the treatment of mastitis in dairy animals. Penicillin, as confirmed by the penicillinase identity test, in concentrations of 0.006 to 1.22 units per milliliter, was found in 43 (3.7%) of the samples. One penicillin-positive sample also appeared to contain streptomycin. Twenty-two additional samples appeared to contain one of the tetracyclines, and one other sample contained bacitracin-like activity. However, there are no specific identity tests for small quantities of these drugs and, therefore, their antibacterial activity cannot unequivocally be attributed to these antibiotics. The results of this most recent survey indicate that the program that was initiated after the third survey has caused a significant decrease in the incidence of penicillin-contaminated milk. In fact, this decrease may be even greater than that shown by the figures because of the difference in sampling techniques used in the 1959 survey and in the previous surveys. In the first three surveys, all samples were collected from milk that had been processed by the dairies and had been delivered to the retail trade. We believe that many of the penicillin-positive samples found in the fourth survey would have been negative if they had been collected after having been diluted with antibiotic-free milk at the dairy, which normally would have been the case. However, the program has not solved completely the problem of penicillin-contaminated milk. It is therefore necessary that other approaches be considered as a solution to this public health problem.

Summary

There are 17 to 20 million individuals in the United States who may react to contact with antibiotics. The physician can avoid unfavorable side-reactions in these people by the discriminate use of antibiotics as therapeutic agents. A greater problem for the physician is the introduction of antibiotics in foods, both directly and indirectly. Antibiotics are used in animal feeds, crop sprays, and as food preservatives. The FDA and other agencies have taken steps to alleviate this problem; however, it has not been solved completely.

ANNOUNCEMENT

A monograph of the five papers presented at the symposium on "Nutrition in Pregnancy" in Columbia, Mo., Oct. 11, 1957, is now available. These papers, which were published in THE JOURNAL, include "Nutritional State of the Mother Prior to Conception" by Genevieve Stearns, Ph.D.; "Maternal Nutrition and the Fetus" by Ray Hepner, M.D.; "Production of Congenital Malformations by Dietary Measures (Experiments in Mammals)" by Josef Warkany, M.D.; "Vanderbilt Cooperative Study of Maternal and Infant Nutrition: XII. Effect of Reproductive Cycle on Nutritional Status and Requirements" by William J. McGanity, M.D., F.R.C.S.(C), Edwin B. Bridgforth, A.B., and William J. Darby, M.D., Ph.D.; and "Metabolic and Biochemical Changes in Normal Pregnancy" by Icie G. Macy, Ph.D., Sc.D. The "Nutrition in Pregnancy" monograph may be obtained, free of charge, from the Council office.

COUNCIL ON MEDICAL PHYSICS

Report to the Council

The Council has authorized publication of the following report. The conditions treated and dosages used represent the author's research and experience. They should not be construed as recommendations of the Council, since the final decision as to dosage and use must rest with the individual practitioner who has examined the patient to be treated. Ionizing radiation for ophthalmic conditions should be employed only by those who are experts and are well aware of the dangers of this form of treatment to the patient and to the physician.

RALPH E. DE FOREST, M.D.,
Secretary.

BETA RADIATION SOURCES, USES, AND DANGERS IN TREATMENT OF THE EYE

William F. Hughes, M.D., Chicago

Beta radiation from radium, radon, and radium D-E has been used in the treatment of certain external ocular conditions for about 40 years because of the relatively superficial effects and accurate localization of the radiation. More recently, radioactive strontium (Sr^{90})-yttrium (Y^{90}) applicators have become available as a source of beta particles or electrons for ocular use. The early enthusiastic reports of the efficacy of beta radiation have been tempered by the appearance of certain secondary complications including cataract. Therefore, it becomes more important that the clinician be aware of the sources, rationale, uses, contraindications, dosages, and dangers of beta therapy.

Characteristics of Various Sources of Beta Radiation

Various sources and applicators have differing characteristics in surface output, depth dose, and amount of gamma rays. A comparison of available data[1] on these applicators is given in table 1. The differences in the construction of the applicators, their output, and depth doses are readily apparent. The earlier method of denoting dosages as "gram seconds" or "millicurie minutes" has no meaning unless the individual applicator is standardized, either physically by means of the Failla-type extrapolation (vanishing ion) chamber or biologically on animal and human eyes. Not only are the outputs of different types of applicators with similar amounts

---

of radioactive material different, but applicators of similar design and materials may show significant variations.

Surface Output.—In the past, surface output has been denoted physically as so many reb (roentgen equivalents beta) or rep (roentgen equivalents physical) per second, representing an energy absorption by air of 84 ergs per gram of air per second, or an energy absorption by tissue of 93 ergs per gram of tissue per second. More recently, a new unit of dosage has been officially adopted; namely, a rad, indicating an energy absorption of 100 ergs per gram. Accordingly, for Sr^{90}, 1 rad = 1.19 rep (air) or 1.08 rep (tissue). These numerical values should be considered as guides to clinical dosage rather than be accepted as absolute values. Possible variables include the following factors.

TABLE 1.—*Comparison of Various Sources of Beta Radiation*

Characteristic	Radium		Radon		Radium D-E		Sr^{90}-Y^{90}

* Rad.=unit of absorbed dose.
† Data not available.
‡ Estimated by effects on tissues in comparison with other applicators which have been standardized by physical methods.

1. Uneven distribution of the radioactive substance on the inner surface of the applicator may produce a greater error with the extrapolation chamber than with depth doses determined by photographic film determinations. Such unevenness can be detected by underexposing a photographic film with the active surface of the applicator.

2. Filtration by the radioactive material itself (especially radium or radium D-E) or by the window of the applicator can (*a*) increase the depth dose by filtering out beta particles of less energy, although the rad surface output as measured by the extrapolation chamber may be the same, or (*b*) produce more scatter, affecting the extrapolation chamber more than the film method.

3. The surface output is calculated by extrapolation to zero volume of the ionization chamber, successive readings having been taken of the amount of ionization per unit volume produced by the applicator in progressively smaller quantities of air. Estimation of the ionization in "zero volume" is made from the slope of the curve as volume in the ionization chamber is reduced. Unfortunately, the slope of this curve is constantly changing, and the extrapolated estimate of surface output can be as much as 10% in error.

4. Changes in technique of the extrapolation chamber measurements have been made in the past in an effort to approach an absolute value. This has led to confusion in the clinical use of the strontium applicator based on previously established dosages. Recently, this difficulty has not been experienced in restandardization of the applicators.

5. Leakage of radioactive material can occur, resulting not only in loss of potency of the applicator but also in radiational hazard in the environment. This can be tested for by "wipe tests" such as those in which the surface of the applicator is wiped seven times on filter paper, which is then tested for radioactivity with a Geiger tube. The Geiger tube should have a window thickness resulting in a weight of less than 2 mg. per square centimeter. Under regulations of the Atomic Energy Commission, one would not be authorized to purchase a Sr^{90} applicator unless adequate facilities existed for carrying out a wipe test. Sr^{90} applicators should be rechecked and restandardized, especially if there has been a positive wipe test. The user should also be warned to keep his hands from the front of the applicator when wiping the surface. It is also a good idea to attach to the storage box a decay curve showing the activity over one half-life, e. g., 25 years for the Sr^{90} applicator.

How can an ophthalmologist or radiologist be certain of the clinical effect to be expected from a certain applicator? Evenness of layering of the radioactive material can be checked with x-ray film. The surface output and depth doses can be determined on each applicator by the company which issues the applicator. Biological standardization is the only means at present of determining the output of applicators with unusual shapes and is a valuable check on the physical methods of measurement. This can be performed on the rabbit cornea. The applicator is placed in steady contact with the rabbit cornea, preferably using six corneas for each dose of 15,000, 20,000, 25,000, and 30,000 rad. The minimal dose that produces a faint corneal opacity which does not clear for several weeks has been termed the "Minimal Inflammatory Dose" or "MID" by Wilson. For the Sr^{90} applicator, this is approximately 21,000 rad ± 10%.

Depth Doses.—Surface output does not necessarily indicate clinical effectiveness or possible dangers of cataract formation. Because true absorption or ionization in tissue cannot be measured directly, a measurement in the ionization chamber can be made after the beta particles have passed through varying thicknesses of tissue-equivalent material, for example, polystyrene, lucite, or water. Ideally, selection of beta sources with beta particles of different energies and depth doses might be made with regard to the depth of the lesion to be treated. For example, prevention of the superficial vascularization of a recurrent pterygium would require only surface irradiation, whereas deeper irradiation would be indicated for tumors or deep corneal vascularization. Knowledge of depth doses is also important in relation to possible formation of cataract. In applying contact therapy to the corneal limbus, the sensitive equatorial cells of the lens are only 3 mm. away, whereas the anterior surface of the lens is usually about 4 mm. distant from the apex of the cornea. With this information, an estimate can be made of the amount of radiation reaching the lens. The tolerance of the lens for irradiation will be discussed under dangers of beta radiation.

TABLE 2.—*Relative Proportion in Tissues of Beta and Gamma Radiation from Radon*

Tissue Depth, Mm.	Beta Radiation, %	Gamma Radiation, %
0 (Surface)	96.5	3.5
1	88.0	12.0
2	78.5	21.5
3	67.6	32.4
4	55.5	44.5
5	43.0	57.0

Gamma Rays.—Radium and radon applicators, unlike radium D-E and Sr^{90} applicators, emit gamma radiation in addition to beta radiation. The relative proportion of beta to gamma radiation from radon at various tissue levels is found in table 2. Because of the relatively small amount of gamma radiation in comparison to the beta particles which emerge from radon, a therapeutic dose of beta radiation can be applied to superficial tissue without undue gamma ray absorption in the deeper structures of the eye. The percentage of gamma rays is somewhat greater in radium than in radon applicators because of the absorption of beta particles by the radium mass itself. This results in a loss of clinical potency of beta radiation from the radium applicator, which might be roughly estimated as 15% per unit area for the Iliff applicator. Accordingly, with the radium applicator, a longer exposure time, with consequently more gamma radiation, is necessary to obtain the desired dosage of beta radiation than is the case when radon is used. From a practical standpoint, gamma radiation from beta applicators creates some hazard for the therapist. These applicators should be stored in a lead container with walls, top, and bottom at least one inch in thickness. The lids should be held open by a speculum, by the patient, or by another person not connected with radiation therapy. The maximum permissible dose for the therapist should follow the recommendations of the National Committee on Radiation Protection.[2]

Characteristics of Applicators.—In an effort to encourage more uniformity of beta radiation applicators, certain information about the characteristics of each applicator is desirable, as follows: (1) the quality of radioactive emanations, including the ratio of beta to gamma rays and energy of the beta particles (maximum Mev, average Mev, and depth doses); (2) certification by the National Bureau of Standards or by a qualified laboratory of the quantitative output of each individual applicator in rad surface output; and (3) experimental and clinical trials to corroborate the output.

With the need for the information just outlined, a few comments on the deficiencies of the various applicators are in order. In the radium applicators, the surface output in rad per second has not been standardized physically, the depth doses have not been determined, and biological determination of the MID has not been published.

A specimen of an early model radium D-E applicator was tested for surface output and depth dose, but each individual applicator has not been standardized. Wilson [1d] found that the radium D-E applicator required approximately two and one-half times the dose in gram seconds of radon to produce similar clinical effects in both rabbit and human eyes. This lower clinical potency of the radium D-E applicator is probably the result of the self-absorption of the relatively soft beta particles by the radium D mass itself, plus the smaller depth doses of the less energetic beta particles. Doubling the quantity of radium D in the applicator does not double the output but instead increases the effectiveness by approximately 50%. Because of the relatively low output of the 10-mc. radium D-E applicator, either prolonged treatment times up to 16 minutes are required to eliminate such a condition as superficial corneal vascularization, or repeated exposures within relatively short periods of time (e. g., every week) are required to obtain adequate cumulative effects. These considerations are of some practical importance clinically, because prolonged treatment times increase the difficulty of accurate localization of the radiation and increase the amount of trauma. The relatively low depth dose makes it difficult to obtain adequate dosage in the treatment of such conditions as deep corneal vascularization without excessive damage to the superficial tissues.

The radon applicators have the inherent disadvantage of deterioration (half-life, 3.825 days), and it is practically impossible to standardize each applicator after reloading. Krohmer[1a] measured several radon applicators physically and found that the surface output varied as much as 63%. Also, the construction and shape of some radon applicators have prevented measurement of the output by ionization chambers.

The characteristics just outlined for each applicator are available for Sr^{90} applicators. This assumes that the present physical methods of calibrating the applicators by the issuing companies remain the same, and that one rad surface output today will correspond to one rad surface output on which the clinical dosages have been determined previously.

Use of Beta Radiation

The general uses for beta radiation are the same as for any other type of radiation such as x-ray. The effects of irradiation are destructive, and there must be a differential sensitivity between the pathological cells to be destroyed and the normal cells of the adjacent tissue. The relative sensitivity of cells to radiation has been determined previously by Desjardins[3] and others in the following order of decreasing sensitivity: lymphoid cells, polymorphonuclear cells, eosinophils, epithelium (conjunctiva, cornea, lens, and ciliary), endothelium (vessels, cornea), connective tissue including the cells of the corneal stroma, muscle, bone, and nerve which includes the neural elements of the retina. Among other factors which increase the sensitivity of cells are undifferentiation, immaturity, premitotic stage, active metabolism, and a large blood supply. Very small doses of irradiation are stated to affect favorably infectious processes, although larger doses are detrimental.

Method of Administration.—The method of administration of beta radiation is as follows. Slit-lamp examination is performed to determine the exact area for treatment. Topical anesthesia is then applied and the applicator placed in contact with the lesion. Unless the total dose is purposely fractionated or a severe condition warrants more frequent treatments, at least two to three months should be allowed between treatments in order to observe the maximal beneficial effects of the previous treatment and thus utilize the smallest effective dose. However, as shown in other sections of this paper, determination of maximal deleterious effects requires a greater time interval. When the Sr^{90} applicator is employed, probably not more than 4,000 rad per area of treatment should be used, unless the possibility of later lens opacities is considered to be a legitimate risk. A dose of 1,000 rad may be sufficient for highly sensitive lesions.

Conditions Treated.—Because of the uncertainties in dosage and the development of late complications, beta radiation should be reserved for use in those conditions in which it is superior to other methods of treatment or in which other methods have failed. This conservatism has reduced the number of conditions in which beta radiation is recommended. It is not the purpose of this communication to give in detail the dosages and results of beta radiation therapy in many conditions. Recently, a study has been made of 694 eyes previously treated with radon (60% of cases) or a Sr^{90} applicator.[4] In about half of the cases patients were followed up for over five years, and in some of the early cases patients treated with radon were followed for as long as nine years. In general, the results of treatment and the complications were essentially the same, whether a Sr^{90} applicator or a radon applicator[1b] had been used. As an approximation of dosages of equal clinical effectiveness, one gram second of beta-radon was roughly equivalent to 2,000 rad with the Sr^{90} applicator. The currently recommended dosages in rad given subsequently apply to the Sr^{90} applicator.

Favorable Results of Treatment with Beta Radiation

Corneal Vascularization.—The undesirability of corneal vascularization and the relatively great sensitivity of the endothelium of blood vessels to radiation have led to the use of beta radiation in preventing or eliminating corneal vascularization. In general, superficial vessels are more sensitive to treatment, probably because they receive a larger dose of radiation. Small, actively growing capillaries on the surface are very sensitive, thereby providing an effective means of preventing recurrences of pterygiums after operation. Large trunk vessels, especially when deep, require such large doses of radiation that the long-term results are usually disappointing. The most gratifying results both subjectively and objectively were obtained in cases of rosacea keratitis, which were resistant to local corticosteroid therapy, in which only 2 out of 42 patients remained unimproved and none became worse after radiotherapy. The effective dose in any one quadrant of the cornea necessary to eliminate the corneal vascularization of rosacea keratitis approached the minimal dose which might produce small peripheral opacities in the lens a few years later, namely, 6,000 rad. The primary treatment of pterygiums or their recurrences by beta radiation required unduly large doses to eliminate the well-established vessels. However, beta radiation given within one to two weeks after operation appeared effective, with only 1 case of 42 recurrent cases of pterygiums recurring after this combined treatment; none of 81 cases of primary pterygiums treated with surgery and prophylactic beta radiation developed any recurrence. Although a larger series with proper controls is required for final evaluation, the present management for very vascular or recurrent pterygiums consists of operation, followed one week later with 1,000 to 2,000 rad of beta radiation, repeated once one to three weeks later.

Limbal Tumors.—All 22 cases of tumors at the corneoscleral junction responded well to beta radiation, either with or without partial excision, including papillomas, epithelial plaques, Bowen's disease (epidermoid carcinoma in situ of skin), and epitheliomas (11 cases). A dose of 5,000 rad is recommended for premalignant and malignant tumors, and 3,000 rad for papillomas.

Vernal Catarrh and Allergic (Phlyctenular) Keratitis.— Vernal catarrh and allergic conditions of the conjunctiva and cornea are usually alleviated by the local use of corticosteroids such as hydrocortisone or prednisolone. However, certain cases do not respond satisfactorily or have frequent recurrences. This is particularly true of palpebral vernal catarrh, with large pavement-stone vegetations and ropy discharge, and of allergic keratitis of the lower portion of the cornea associated with superficial vascularization. The effects of beta radiation have been helpful in most of these cases. In general, doses of 5,000 rad are given to each area of the vernal catarrh on the upper lids, care being taken not to expose the roots of the lashes. Such doses can be repeated once or twice, if necessary, after several weeks or a few months. For limbal lesions of this type, doses as low as 1,000 to 2,000 rad, perhaps repeated once after a few weeks, may be sufficient to eliminate this allergic type of tissue and superficial vascularization.

Conjunctival Papillomas and Hemangiomas.— These benign tumors are very sensitive to beta radiation and can often be eliminated by doses as low as 2,000 rad.

Trichiasis.—The dosage required for permanent epilation is uncertain, but it can usually be accomplished by 3,000 rad of beta radiation. However, the eyeball should be carefully shielded.

Variable Results of Treatment with Beta Radiation

Good results were obtained in only 30 to 40% of the following types of corneal vascularization: primary vascularizing keratitis, indolent corneal ulcer, chemical burns, effects following corneal transplantation, scars of unknown etiology, trachoma, corneal dystrophy, and keratoconus. Six cases of interstitial keratitis showed no change attributable to the radiation. Although various types of keratitis, episcleritis, and scleritis often showed improvement after treatment with very low doses (500 to 1,000 rad) of beta radiation, it could not be determined whether this was significantly related to the radiotherapy. Although granulation tissue is sensitive to radiation, the results after beta radiation therapy were variable, possibly because the depth dose was insufficient to reach the deeper portions of the granulation tissue usually located within the tarsus of the lid. Therefore, it is inadvisable to use this radiation to treat such granulation tissue. Merriam[5] reported that precancerous melanosis of the conjunctiva responds satisfactorily to 3,000 to 5,000 rad of beta radiation.

Contraindications for Use

Beta radiation should not be used for several conditions because of lack of effect, better treatment available, or undesirable complications. These include tumors of the lid margin, nevi of the conjunctiva, pinguecula, primary treatment of pterygiums without immediately preceding surgery, pemphigus, corneal scars without vascularization, Fuchs' endothelial-epithelial dystrophy, epithelial downgrowths into the anterior chamber, acute chemical burns, and inflammatory lesions, requiring large doses.

Complications of Beta Radiation

Cataracts.—Any opacity in the lens, with or without reduction in vision, is termed a cataract. With this definition, cataracts have been observed in both rabbits and humans after beta radiation from radium, radon, and Sr^{90} applicators.[6] Treatment over the limbus is most likely to produce lens opacities because the sensitive germinative cells at the equator of the lens are only 3 mm. away from the surface of the limbus, and from 4 to 18% of the surface dose from these applicators reaches this area.

In the study referred to previously,[4] no radiation cataracts were observed in any of the 192 patients treated for conditions of the lids. A total of 213 eyes, which had received beta radiation treatment to the globe, were examined to determine the presence or absence of radiational lens opacities. Of these, 45% had definite radiational opacities, and 12% had probable radiational opacities. The earliest cataracts were seen two and one-half years after treatment, larger doses producing opacities somewhat earlier than smaller doses. The smallest dose which produced equatorial vacuoles in the lens was 4 gram seconds when the radon applicator was used and 5,000 rad when the Sr^{90} applicator was used. On the other hand, other eyes showed no evidence of cataracts for as long as eight years after exposure to 12 gram seconds of radon or three years after exposure to 7,000 rad of strontium^{90}. Peripheral radiational vacuoles in the lens usually assumed a wedge-shaped configuration and, with larger doses of radiation, migrated posteriorly. Of the cases observed both in 1953 and 1957, 79% showed progression of the opacities, 11% no progression, and 9% showed actual regression. Of 121 eyes with definite or probable radiational opacities, 19 previously treated with radon and 7 previously treated with Sr^{90} had opacities which reached the posterior pole of lens where they might have interfered with vision. Two beta radiation cataracts were extracted, and three additional cataracts were extracted from eyes which had received both x-ray and beta radiation.

Other Complications.—A year or more after administration of doses as low as 7,000 rad to the conjunctiva, telangiectases developed in and around the area of radiation. In one-third of these cases, these postradiational vessels created a real cosmetic blemish, especially when located within the palpebral fissure. Interference with wound healing was noted in approximately half of the 17 corneal transplantations and 10 cataract extractions performed on eyes which had been treated with beta radiation from six months to nine years prior to surgery. This confirms the previous experimental results in rabbits.[7] Since radiation is primarily destructive, the therapist must be careful to avoid accentuation of necrosis and ulceration already present. This is particularly true of acute chemical burns, corneal ulcers, and inflammatory processes.

Summary

Beta-radiation ophthalmic applicators, particularly the radioactive strontium (Sr^{90})-yttrium (Y^{90}) applicator, provide a ready source of radiotherapy for superficial lesions of the eyes. The general indications for beta radiation of the eye are the same as those for other forms of radiation such as x-ray. Because the therapeutic dosage and the dosage which might result in later complications are fairly close, exact knowledge must be obtained concerning the output of the applicator in rad per second, the depth dose, biological standardization, and the differential sensitivity of the tissues to be destroyed compared with the normal ocular tissues. This is particularly important when radiation is given over the region of the limbus which is only 3 mm. away from the sensitive equatorial region of the lens. Minimal cataractogenic doses appear, at this time, to be approximately 5,000 rad at the applicator surface with the Sr^{90} applicator when applied over the limbus. Minimal lens opacities in the periphery do not necessarily progress or affect vision, and certain serious ocular conditions requiring beta radiation warrant the necessary risk of producing a cataract later. In general, beta radiation should be reserved for use in those ocular conditions in which it is superior to other methods of treatment or in which other methods have failed.

ACCIDENTS IN CHILDHOOD.—The death rates from accidents actually declined 42 per cent from 1928 to 1957. This decline is primarily due to improvement in the care of the victim and not the result of a decrease in the rate of accidental injury. During the same period, however, mortality from most other causes in childhood declined even more dramatically, leaving accidents as the most common serious health problem of childhood today. Home accidents account for 38 per cent of all accidental deaths in children under fifteen years of age, and in the age group under five, 58 percent of accidental deaths occur in or about the home.—R. J. Haggerty, M.D., Home Accidents in Childhood, *The New England Journal of Medicine,* June 25, 1959.

PROBLEMS OF IMPAIRED SPEECH AND LANGUAGE

GUEST EDITORIAL

Wendell Johnson, Ph.D.

THE process of symbolization is the most distinctively human of man's bodily functions. The clinically recognized impairments of the symbolization process are primarily those of spoken language. Disorders of spoken language involve impaired phonation, speech sound articulation, fluency and rate, or symbolic representation, singly or in combination, associated or not with significant organic or physiological complications or emotional disturbance.

The clinically significant organic or physiological conditions most often associated with speech problems are those related to hearing loss, cleft palate, laryngectomy, cerebral palsy or other types of neuromuscular impairment, brain damage including cerebrovascular accident with attendant aphasia and dysarthria, and retarded or limited development affecting language and speech. Associated emotional reactions are rather more likely to be effects than causes of the speech disorder, and are, in any event, interactive with it.

The magnitude of the problem is suggested in part by current estimates of incidence. I recently had occasion to appraise relevant aspects of the situation for the United States Office of Education and concluded that probably 4% of all children enrolled in the public and private elementary and secondary schools of the United States have socially and educationally significant speech problems.[1] This amounts to a total of 1,600,000, assuming a national public and private school enrollment of 40 million. About 1 million of these children present faults of articulation, such as lisping, not associated with organic pathology. About 280,000 school children stutter, 200,000 have impaired speech associated with hearing loss, 40,000 have voice problems, and about 20,000 present each of the following faults: fluency and rate problems, retarded speech development, speech difficulties related to cleft palate and lip, and problems of speech and voice associated with cerebral palsy and other types of disturbed neuromuscular functioning.

Incidence data for adults are limited. There are, certainly, relatively more cases of functional misarticulation among children and more cases of aphasia and impaired speech and voice associated with laryngectomy and vocal cord pathology among adults. Stuttering affects from 6 to 8 per thousand children and college-age adults, but the incidence for more advanced age levels has not been well determined. Decreased auditory acuity and other effects of aging tend to be reflected in modified speech and language, with varying degrees of personal and social significance.

Present knowledge indicates that, by conservative estimate, there are probably 2,500,000 children and adults in the United States with speech, voice, and language impairments of relatively severe grade.[2]

The problems presented by these 2,500,000 persons are both medical and nonmedical, and they are most constructively managed through flexible patterns of multidisciplinary cooperation, varying with the needs of specific speakers. The medical specialists most often concerned with conditions functionally related to speech, voice, and language disorders are the otolaryngologists, oral surgeons, neurologists, neurosurgeons, orthopedic surgeons, psychiatrists, pediatricians, and general practitioners.

The nonmedical profession that has developed in response to the growing demand for educational and remedial services in this field is that of speech pathology and audiology, representing the speech and hearing sides of the coin of impaired communication.[3] This profession functions through the American Speech and Hearing Association (1001 Connecticut Ave. N. W., Washington 6, D. C.), which administers clinical certification for its members at basic and advanced levels in speech and hearing, respectively, publishes the *Journal of Speech and Hearing Disorders* and the *Journal of Speech and Hearing Research,* and seeks to improve the research and professional training programs and the educational and clinical services within its sphere of responsibility. Two-thirds of its roughly 5,000 members hold graduate degrees, and some members are physicians.

As a profession, speech pathology and audiology synthesizes the resources of several scholarly and scientific fields, particularly phonetics, semantics, psychology, psychoacoustics, genetics, anatomy, physiology, and neurology, as well as education, sociology, and cultural anthropology. Within the resultant interdisciplinary framework a growing body of research data, theory, and clinical technique has been accumulated. The number of uni-

versities with departments of speech pathology and audiology and graduate programs in the field is gradually increasing. An estimated 1,000 to 1,200 graduates at all degree levels are being trained annually and an increasing refinement of the profession's standards of training parallels its growth. Other professions which contribute substantially to the effectiveness of services for persons with speech impairment are dentistry, particularly orthodontia and prosthodontia, education, and clinical psychology.

Speech correctionists do their work for the most part in two general settings: (*a*) the schools and (*b*) university and community speech and hearing clinics, hospitals, hospital-schools, rehabilitation centers, and institutions for the handicapped or retarded. So far as sheer number of cases is concerned, most speech correction is done in the public schools, primarily in the early grades. Most public school speech correction cases are those involving speech sound misarticulation without organic or severe emotional complications. Although school personnel commonly devote time to persons with organic speech problems and to those with complex emotional involvements, the services rendered tend to be demanding and extremely time-consuming. Moreover, they must be coordinated with essential medical and surgical measures, and as a consequence these more complex speech problems are generally dealt with wholly or in part in speech clinics outside the school.[4] Many universities conduct intensive summer speech clinics for school-age children.

Since speech correction is severely demanding of time and attention to detail,[5] and because of the nonmedical character of the required specialized training, it is the exceptional physician who is disposed to prepare himself by formal training to assume responsibility for speech correction, per se. Meanwhile, most physicians have a constant opportunity and ever-recurring obligation to consult with professional workers in speech pathology or to secure for their patients needed speech correction services. This is particularly true in patients requiring surgery that clearly or possibly will affect the speech function, as in cleft palate repair and laryngectomy. It is true as well in the development of an optimal rehabilitation program in any case of neuromuscular dysfunctioning involving the speech mechanism. Adequate treatment and care in cases of cerebrovascular accident necessarily include appropriate speech and language appraisal and indicated retraining procedures. Maximally effective treatment for patients with impaired hearing involves, as a matter of course, not only essential audiological measures with respect to hearing aids and auditory training but instruction and counseling designed to restore or preserve clear and well-modulated speech.

Pediatricians and general practitioners have frequent need to give counsel in response to parental concern over childhood speech—especially when such concern is not justified and is most likely, therefore, to have harmful effects. Little doubt remains that stuttering, for example, originates primarily in the disturbing perceptions and judgments of the listening parent responding with ill-informed preconceptions to the child's normally hesitant early attempts to negotiate the intricate neuromuscular and psychosocial complexities of spoken language.[5] We know now that the problem we call stuttering is not to be confused with the matter (it is seldom a problem) of speech nonfluency, per se.

Considerable research to date provides no appreciable support for the hypothesis that stuttering is characteristically associated with or symptomatic of severe emotional disturbance or neurosis in a clinically significant sense.[7] The counseling and retraining procedures needed by adolescent and adult stutterers, as well as by most persons with other types of impaired speech, appear to be, in their own way, of a piece with those required by the handicapped and mistutored rather than the neurotic or emotionally unstable.

The significance of the process of symbolization in relation to health and disease awaits the definitive scientific appraisal that its distinctively human character urgently warrants. Its role in the iatrogenic[8] and semantogenic[9] disorders would appear to be basic. It seems likely that it provides the major mechanism for psychosomatic reactions and for the patient's mode of adjustment to illness of whatever sort—and to wellness. The overriding consideration is that symbolization is a bodily process, mediated by the nervous system, and that it interacts necessarily with other bodily functions. There is little to be said for disregarding its gross disorders; there is much to recommend sophisticated attention to its seemingly minor but innumerable miscarriages.

ORGANIZATION SECTION

STATEMENT TO SUBCOMMITTEE ON HEALTH AND SAFETY

July 6, 1959

Hon. Kenneth A. Roberts, Chairman
Subcommittee on Health and Safety
Committee on Interstate and Foreign Commerce
House of Representatives
Washington 25, D. C.

Dear Congressman Roberts:

This will acknowledge with thanks the notices dated June 18, 1959, addressed to me as Executive Vice President of the American Medical Association, and to Dr. Fletcher D. Woodward, the Chairman of our Committee on Medical Aspects of Automobile Injuries and Deaths. With your permission the Association would like to submit this statement for inclusion in the printed record of the hearings on the measures outlined in the notice of June 18.

Inasmuch as the American Medical Association has not considered or taken a position on most of the specific bills under consideration by your Committee, our statement will be general in nature. It will, however, I believe, outline the extent of our interest in this field and underscore our conviction that regulatory action at an early date is imperative.

The American Medical Association has been concerned with the problem of automobile injuries and deaths for many years. Actions of our House of Delegates on this subject are numerous and date back as far as 1929. In 1948, our House passed the following Resolution:

> WHEREAS, The American Medical Association has in the past cooperated with the National Safety Council in its efforts to reduce the incidence of deaths and injuries from accidental causes; and
>
> WHEREAS, The studies that have been made by the Bureau of Medical Economic Research of the American Medical Association have established the fact that fatal accidents cut off more years from the working lifetime of the American people than any one natural cause of death, and
>
> WHEREAS, In the recent report made to the President by the administrator of the Federal Security Agency, it was stated that 40,000 deaths annually from accidents were preventable; therefore be it
>
> *Resolved,* That the Board of Trustees be instructed to cooperate in every possible way with the National Safety Council and with every other agency, both public and private, concerned with accident prevention, to the end that research in accident prevention be further stimulated; that this excessive drain on hospital and medical facilities be lessened, and that the appalling loss of working years be reduced.

For more than 30 years our Association has had Committees actively working on the various aspects of the automobile accident problem. The present Committee, known as the Committee on Medical Aspects of Automobile Injuries and Deaths, was appointed by our Board of Trustees in 1955. Its members are chosen from physicians who by their interest and work are considered to be well qualified in this field.

We believe most people will agree that those who are called upon night and day to pronounce dead those persons killed on our highways, and who mend the broken bodies of those who are injured, can well be classified as interested and qualified in their efforts to prevent such carnage. Within the lifetime of most of us, we have seen substantial gains by the medical and allied health professions in the conquest of disease and disability. Many of the diseases that were commonplace early in this century have been conquered or brought under effective control. Many diseases that were once widespread are now a rarity. However, accidental injuries and disabilities due to automobile accidents have become the number one public health problem of our time. We believe it is important, therefore, that the medical profession continue to increase its interest in the automobile accident problem until effective improvement is a reality.

As the result of our studies, we are convinced that if speed, recklessness and drunken driving are controlled, and if improvements in automobile engineering are provided to protect those involved in collisions, then the present appalling toll of injuries can be substantially reduced. We are further convinced that enough facts are at hand to accomplish this purpose.

One of our most important objectives has been to provide the practicing physician with technical medical information which will enable him to advise and inform his patients relative to driving limitations that may be involved because of the effects of drugs or alcohol or the existence of physiological, pathological or emotional conditions.

We realize that a certain percentage of accidents are undoubtedly caused directly or indirectly by medical conditions, drugs, and other related physical factors. In an effort to identify these problems and to develop workable solutions, we sponsored a symposium on Medical Aspects of Automobile Injuries and Deaths at the Association's Annual Meeting in June, 1956, in Chicago, and in June, 1958, in San Francisco. Papers presented at these meetings were published in THE JOURNAL of the American Medical Association on January 26, 1957, and April 4, 1959. Reprints are attached for you and for the members of your Committee.

Our next objective was to prepare a comprehensive book to serve as a guide to physicians in determining fitness to drive as related to the medical background of the individual. This book, a copy of which is attached, represents a compilation of medical data and the opinions of nationally recognized authorities in the various special fields of medical practice. With this information available, it should be possible for the individual physician to make a significant contribution to the welfare of his personal patients and the public at large.

Closely related to the need for factual information to aid the physician is the need to inform the driving public, through use of proper media, of the medical conditions which may affect their driving proficiency. We believe that many individuals would voluntarily discontinue or diminish radically their driving if they understood the dangerous possibilities involved in certain physical disorders and the potential effects of certain medications. In other words, we believe the technical information furnished the physician should be supplemented with a pamphlet written at the popular level and covering the more commonly encountered medical situations. In this way the patient can have the advantage of written information which will serve to instruct him as to whether he should or should not drive; and, if so, under what safeguards. Such a pamphlet, entitled "Are You Fit to Drive?" has been prepared by our Committee on Medical Aspects of Automobile Injuries and Deaths, in cooperation with the Center for Safety Education of New York University.

There is little doubt that a great deal of attention must be given to the very serious question of who shall be permitted to drive an automobile and who shall be denied that privilege. We emphasize that driving should be a privilege rather than a right. Therefore, our third objective is to develop better medical standards for driver licensing, including preparation of a guide for license examiners and assistance to state agencies concerned with licensing. This will be based on the information compiled in the medical criteria mentioned earlier and will constitute our recommendations for state licensing agencies. We recommend that each state medical society have a committee on traffic safety, with objectives such as those outlined on the attached green sheet. Such committees would be in a position to advise and assist state driver licensing bodies in the improvement of medical standards for licensing.

Another objective is to study and report on the design features of automobiles. Improvement of the design and safety equipment of automobiles promises the greatest possibility for rapid reduction in the automobile injury and death toll. If it is estimated that the average life of an automobile is ten years, it is apparent that a very considerable reduction in the severity of injuries and a marked reduction in fatalities could be accomplished in that time if more attention were devoted to providing safety rather than to increased horsepower, streamlining, color, and chrome.

The engineers and designers of the automobile—a relative handful of men in the industry—virtually control the destinies of the American public on the highways. They are the men who decide which elements of safety design will be put into or left out of next year's new automobile.

There is presently available an ample body of research data which clearly indicates the definite values of certain safety features of automobile design, construction and equipment. Yet, these safety features, if available at all, are all too often offered as optional equipment at extra cost. The automobile industry can make a great contribution toward solution of this problem by consulting with physicians, anthropologists, psychologists, related biological scientists, and other scientific professions, and by giving realistic consideration to the wide range of physical characteristics of automobile drivers and riders and what happens to them in a collision.

In the past the automobile industry has made many important contributions to safety. However, in recent years, safety has generally been ignored in favor of other developments. The following suggestions have been repeatedly advanced by physicians, researchers, and safety engineers with but little success:

1. Anchorage for seat belts should be standard equipment. The public also needs education in the value of seat belts. The only evidence so far presented against seat belts is in the number of deaths in sports cars during roll-overs. This is not an argument against seat belts but against the design of such cars which do not provide roll-over bars. It should be quite simple to incorporate such a bar in the windshield and a second one back of the seat.
2. Crash padding of the dash, roof, and other areas should be provided.
3. An improved steering wheel and recessed post; perhaps a collapsible assembly.
4. Safety door locks should be standard in all cars.
5. Removal of dangerous knobs, buttons, sharp edges, and other gadgets.
6. Seats should be securely anchored to the floor of the car and should be locked into position. They should also be high enough in the center to protect the neck in a rear-end impact and prevent neck-snap injury (also called whiplash).

7. Eliminate the deck behind the rear seat as a storage place for flying missiles or provide it with an effective retaining rail or construct it as a recessed pocket.
8. Eliminate sharp, pointed hood ornaments. These fill no functional need and are potentially lethal to pedestrians.
9. Eliminate other hazardous exterior design features such as sharp, pointed bumper ornaments.

In addition, we feel that the automobile industry should make an open-minded examination of other suggestions and adopt them where feasible. For example:

1. Shock-absorbing bumpers: if one drives his car into a brick wall at one mile per hour, he will be astounded at the shock transmitted by such an impact. One person testifying last year intimated that to absorb the energy at 20 miles per hour in a 4,000-pound car, such a bumper would have to be 16 feet long.
2. Polarized headlight lenses and an oppositely polarized windshield spot. They would prevent glare at night and thereby prevent many pedestrian accidents and deaths.
3. Consideration should be given to the design of windshield and rear windows to meet standards based on optical principles.
4. Provide protective side-swipe bumpers along the sides.
5. Provide warning reflectors on the sides.
6. Remove tail lights from the realm of the artistic designer.
7. Provide a positive separation of turn signal lights from other lights.
8. Eliminate the glare-reflecting surfaces on the interior.
9. Provide accurate speedometers. Why do we have speedometer dials indicating up to 120 miles per hour? Why not an audible warning device to denote when safe speed has been passed?
10. Construct drivers' seats with better regard for the posture and visibility of persons of various heights.
11. Make chrome, clocks, radiator ornaments and other expensive gadgets optional equipment and install safety equipment as standard equipment.

The following Resolution adopted by the House of Delegates of the American Medical Association at its meeting in Boston on December 1, 1955, is evidence of the interest in this subject by the entire medical profession and the conviction that something constructive can and should be done toward the prevention of injuries:

> Whereas, Traffic accidents in the United States claim 38,000 lives and 1,250,000 injured each year, with a probable 45% increase in vehicle mileage in the next ten years; and
>
> Whereas, This death and accident toll could be materially reduced through improvement in automotive safety design and construction; and
>
> Whereas, All other modes of public transportation except automobile are already safeguarded by Federal safety standards; therefore be it
>
> *Resolved,* That the American Medical Association, through its House of Delegates, strongly urges the President of the United States to request legislation from Congress authorizing the appointment of a national body to approve and regulate safety standards of automobile construction.

On January 9, 1956, Dr. George F. Lull, who was at that time Secretary and General Manager of the Association, addressed a letter to President Eisenhower in which he directed attention to the Resolution.

Another objective of the Association is to promote the extension of emergency first aid training to as many citizens as possible. This training will be of value not only in connection with the reduction of the severity of automobile crash injuries, but also in connection with civil defense needs as well. We feel it is also desirable, therefore, that all automobiles be equipped with first aid kits.

Related to first aid is another objective—to assist in the promulgation and to promote the use of standards for organized emergency services in local communities, including training of rescue squads and standardized equipment for rescue vehicles. This is a future activity in which we will work through state and county medical societies. An example of one problem in this area is the need for better selection, education and control of drivers of emergency vehicles.

As citizens and physicians, we recognize the importance of driving courses for all high school students. Similar courses should be provided for the public and the curriculum should meet certain basic educational requirements. We sincerely hope the day will soon come when such certificates will be required of all prospective drivers as well as for repeat traffic law violators.

Since speed and driving under the influence of alcohol and their related offenses are intimately associated, we feel that strict legislation in this field should be provided. The public needs to be aroused to the point whereby the legislators will provide these laws and the traffic courts will administer them without fear and with complete impartiality.

Because of the indefatigable work of many safety organizations over the years, the incidence of death has been greatly reduced in spite of the tremendous increase in the number of vehicles and number of miles traveled. In spite of this apparent success as to the incidence rate, the total number of deaths and injuries is increasing each year. Unless some of the suggestions mentioned above are followed, it seems inevitable that this number will continue to increase despite the splendid work now being done.

Your willingness to permit the American Medical Association to present its views with respect to the legislative proposals under consideration by your Committee is sincerely appreciated.

Sincerely yours,
F. J. L. Blasingame, M.D.
Executive Vice-President

STATEMENT OF DR. GEORGE M. FISTER ON H. R. 10, BEFORE FINANCE COMMITTEE OF SENATE

Mr. Chairman and Members of the Committee:

I am Dr. George M. Fister of Ogden, Utah, where I am engaged in the private practice of medicine. I am a member of the Board of Trustees and the Chairman of the Council on Legislative Activities of the American Medical Association. With me is Dr. Vincent W. Archer of Charlottesville, Virginia, a member of the American Medical Association's House of Delegates and a member of our Committee on Federal Medical Services.

We are here today as representatives of the American Medical Association to express the wholehearted support of the medical profession for H. R. 10, 86th Congress, a bill which, if enacted, would provide a measure of tax equity for the self-employed including physicians in private practice.

I shall not review or attempt to summarize the provisions of the pending bill since I am sure that you are all completely familiar with the measure. I would like to restate very briefly, however, the history of the support of legislation of this type by the American Medical Association.

In 1948 our Board of Trustees was apprised of a movement to encourage the enactment of Federal legislation which would enable self-employed persons, including physicians, to provide for their own retirement benefits through the payment of amounts annually from their taxable income to finance retirement plans. The Board approved this movement, suggesting that there be a reasonable limitation on such retirement benefits. This action was endorsed by our House of Delegates, the governing body of the Association, at its meeting in June, 1948.

In June, 1951, at the annual session of the American Medical Association, three resolutions emphasizing our endorsement of this principle were adopted by the House of Delegates. On numerous occasions since that time the House has reiterated this endorsement and has recommended that each member of the Association give the matter his careful study and active support.

In the 82nd, 83rd, 84th and 85th Congresses, the Association, through its representatives, expressed support of this type of legislation before the Ways and Means Committee of the House of Representatives. A similar expression of support was communicated by letter to that Committee earlier this year. We have also collaborated closely with representatives of the American Bar Association, the original sponsors of this measure, and other national organizations of self-employed taxpayers who would be covered by the provisions of the bill.

It is the belief of the American Medical Association that physicians, dentists, farmers, lawyers, architects, veterinarians, merchants, and the many others who comprise the nation's self-employed have long been neglected in Federal tax legislation relating to pensions. Under existing law, corporations are entitled to set aside tax-free money to purchase pensions and annuities for their employees, and millions of employees are benefiting from that arrangement. With high taxes and inflated living costs, it is difficult for the self-employed person to set aside adequate funds for retirement without a tax deferment similar to that available to corporate employees. The purpose of this bill is to eliminate this discrimination and inequity. By extending the tax deferment privilege to the country's eleven million self-employed, this legislation will give them an opportunity during their best earning years to save for their old age.

Unless something is done to make self-employment as financially attractive as employee status, we believe that there is a real danger that many professional men will bypass the private practice of their profession. A shift away from individual enterprise has become noticeable in the past few years. A continuation of this situation may not only limit individual initiative but may also create a shortage of medical services in certain areas. For example, it could contribute to a maldistribution of physicians since it makes the large city more attractive to the young professional man by providing more opportunities for him to become employed. I am convinced that the enactment of this legislation would make the smaller communities of America better able to compete with the big cities for the services of physicians.

On the basis of my own observations over many years of practice in medicine, I am convinced that this is one of the factors contributing to the pronounced migration of professional people into urban areas. So, quite apart from the objective of obtaining tax equality with our employed counterparts, we urge you to approve legislation of this type, because it is in the public interest.

This legislation will be of particular benefit to physicians and other professional men who go through a long and costly period of training, and whose earnings are received in a comparatively short period of years when they are subject to high income tax rates.

Under the program proposed in the pending bill, the amount of each person's pension would be determined by his own contributions, without any funds being added by the government. In addition, the program would have the advantage of not forcing an individual into idle retirement in order to draw upon his pension fund. Most important, it presents an opportunity for the self-employed to provide for their own retirement without undue discrimination.

Because such a law will remove the existent discrimination against the self-employed citizen, the American Medical Association strongly urges its favorable consideration by your Committee.

Mr. Chairman, let me take this opportunity to thank you and the Committee for allowing us to express the views of the American Medical Association on this important measure. Dr. Archer and I will be happy to answer any questions the Committee may have.

WOMAN'S AUXILIARY

1959-1960 National Officers and Directors

President: Mrs. Frank Gastineau, 5344 N. Pennsylvania St., Indianapolis 20.

President-elect: Mrs. William Mackersie, 18205 Roselawn Ave., Detroit 21.

First Vice-president: Mrs. Charles L. Goodhand, 1228 Washington Ave., Parkersburg, W. Va.

Regional Vice-presidents:
- Eastern: Mrs. Paul E. Rauschenbach, 612 E. 29th St., Paterson 4, N. J.
- North Central: Mrs. Stephen C. Bacheller, Enderlin, N. D.
- Southern: Mrs. William G. Thuss, 2837 Southwood Rd., Birmingham 13, Ala.
- Western: Mrs. L. D. Jacobson, 1520 Prospect Dr., Eugene, Ore.

Constitutional Secretary: Mrs. W. W. Hubbard, 3711 Mayfair Ave., Nashville 12, Tenn.

Treasurer: Mrs. Harlan English, 6 W. Raymond Ave., Danville, Ill.

Directors for two years: Mrs. Roger H. Cheney, 62 Bellevue Ave., Springfield, Mass.; Mrs. Albert E. Goldstein, 3505 N. Charles St., Baltimore 18; Mrs. Stanley R. Truman, 50 Stark Knoll Place, Oakland 18, Calif.

Directors for one year: Mrs. E. Arthur Underwood, 3725 Wauna Vista Dr., Vancouver, Wash.; Mrs. Shelley C. Davis, 1259 Peachtree Battle Ave., Atlanta, Ga.; Mrs. William H. Evans, 291 Park Ave., Youngstown 4, Ohio; Mrs. M. A. Gold, 509 S. Crystal St., Butte, Mont.

Finance Secretary: Mrs. Harry F. Pohlmann, 29 Railroad Ave., Middletown, N. Y.

Historian: Mrs. George Turner, 3009 Silver Ave., El Paso, Texas

Parliamentarian: Mrs. Mason G. Lawson, 200 Ridgeway, Little Rock, Ark.

Executive Secretary: Miss Margaret N. Wolfe, 535 N. Dearborn St., Chicago 10.

1959-1960 National Committee Chairmen

American Medical Education Foundation: Mrs. Karl F. Ritter, 1420 Shawnee Rd., Lima, Ohio

Bulletin Circulation: Mrs. F. Erwin Tracy, 202 Old Mill Rd., Middletown, Conn.

Bylaws: Mrs. C. Rodney Stoltz, 710 Third St., N. W., Watertown, S. D.

Civil Defense: Mrs. Neil W. Woodward, 4301 Lincoln Blvd., Oklahoma City 5.

Community Service: Mrs. John Wagner, 112 Colburn Ave., Clarks Summit, Pa.

Finance: Mrs. Harry F. Pohlmann, 29 Railroad Ave., Middletown, N. Y.

Legislation: Mrs. Leo Smith, 1507 St. Mary's Drive, Waycross, Ga.

Vice-chairman: Mrs. James D. Morrison, 1002 N. 31st St., Billings, Mont.

Membership: Mrs. Charles L. Goodhand, 1228 Washington Ave., Parkersburg, W. Va.

Mental Health: Mrs. Aaron Margulis, 1664 Cerro Gordo Rd., Santa Fe, N. Mex.

Paramedical Careers Recruitment: Mrs. Lawrence A. Rapee, 6812 Bradgrove Cr., Bethesda 14, Md.

Program: Mrs. Rudolph T. Unruh, 1132 Marsh St., Kinsley, Kan.

Publications: Mrs. E. M. Egan, 6741 S. Euclid Ave., Chicago 49.

Reports: Mrs. Roger H. Cheney, 62 Bellevue Ave., Springfield, Mass.

Safety: Mrs. Samuel S. Lombardo, 4358 Landover Dr., Jacksonville, Fla.

DR. BRAMLITT TO BE SECRETARY OF COUNCIL ON SCIENTIFIC ASSEMBLY

Dr. Charles H. Bramlitt, recently retired from the U. S. Air Force and currently Secretary of the Section on Military Medicine of the Scientific Assembly of the American Medical Association, will become a member of the staff of the American Medical Association on Aug. 1 and will work with Dr. Hull. When Dr. Hull retires as Secretary of the Council on Scientific Assembly at the end of the year Dr. Bramlitt will become Secretary.

CHANGE OF ADDRESS

If you change your address please notify THE JOURNAL at least six weeks before the change is made. Include the address label clipped from your latest copy of THE JOURNAL, being sure to clearly state both your old and new address. If your city has Postal Zone Numbers, be sure to include this Zone Number in your new address.

MEDICAL NEWS

CALIFORNIA

Ophthalmologist Honored.—A special number of the *American Journal of Ophthalmology* has been dedicated to Dr. Frederick C. Cordes, San Francisco, chairman, department of ophthalmology, University of California School of Medicine. This issue was dedicated to Dr. Cordes on the occasion of his 67th birthday and his retirement from the faculty. He has been department chairman since 1934 and a member of the U. C. Medical Center staff since earning his M.D. degree there in 1918. The issue contains tributes to Dr. Cordes' accomplishments in medical education and the study of eye diseases by several distinguished ophthalmologists and by associates in the university, including President Emeritus Robert Gordon Sproul.

Personal.—Dr. James N. Waggoner, Chicago, regional medical director for United Air Lines, has joined the Garrett Corporation's AiResearch Manufacturing Division of Los Angeles as medical director.——Dr. Howard R. Bierman resigned as director, Hospital for Blood Diseases and Medical Oncology, and scientific director, City of Hope National Medical Center, Duarte, to enter practice as a consultant in neoplastic diseases, the leukemias, and blood dyscrasias. He is establishing practice in Beverly Hills and will continue his research program. He will continue as a consultant to the City of Hope, with which he had been associated since 1953.

CONNECTICUT

University News.—Dr. Paul Howard-Flanders, of London, England, was appointed associate professor of radiology, Yale School of Medicine, New Haven. Dr. Howard-Flanders served as a lecturer in biophysics at the University of California in 1957-1958. At Yale he will conduct research in fundamental problems concerning the effect of ionizing radiation on biological systems.——Dr. Edith B. Jackson, child psychiatrist at the Yale School of Medicine, is retiring this summer after more than 25 years on the faculty. Dr. Jackson was director of the "rooming-in" project at the Yale-New Haven Medical Center from 1946 to 1951. In honor of her retirement, her colleagues and friends have given to Yale a portrait of Dr. Jackson, which will hang in the Grover F. Powers Pediatric Study of the Medical Center.

FLORIDA

International Dermatology Symposium.—An International Symposium on Griseofulvin and Dermatomycoses will be held at the University of Miami School of Medicine, Oct. 26-27. Under the sponsorship of the medical school's department of medicine, 50 American and foreign authorities will discuss the mechanism of action of Griseofulvin, its experimental toxicology, and its use in fungous diseases of the hair, skin, and nails. Among those scheduled to give papers are Dr. A. Kaminsky, Buenos Aires Medical School; Dr. F. Latapi, Medical School of Mexico City; Dr. S. C. Desai, Medical College of Bombay; and Dr. R. S. C. Aytoun and Dr. A. H. Campbell, of Glaxo Laboratories (England). The use of Griseofulvin in onychomyocosis, tinea pedis and capitis, favus, endothrix *Trichophyton* infections, and deep mycoses will be discussed, as well as laboratory, animal, and experimental studies on the drug. Information may be obtained from Dr. Harvey Blank, professor of dermatology, University of Miami School of Medicine, Miami, Fla.

State Residency Required for Miami School.—The University of Miami School of Medicine, which has previously required a seven-year residence in Florida for admission to its classes, will, beginning Aug. 6, admit students if they have legal residence in the state. This period has been set at one year by the state authorities. The law affecting the admission of students to the medical school here was changed by the State Legislature at the recent session, it was announced by Dr. Homer F. Marsh, dean of the school. By the terms of the subsidy granted to the school by the State of Florida, 90% of the student body must be residents of the state. The definition of residence has been modified so that the medical school admission requirement is now the same as that for the universities operated by the state itself. The medical school has for the past two years admitted five out-of-state residents and about 70 Floridians to each freshman class. Prior to 1957 no out-of-state applicants were admitted. The medical school, opened in 1952, graduated its first class in 1956 and now has 178 alumni. The freshman class to be admitted in September will number about 75 students. Total number of students in the school now is 270.

ILLINOIS

Mental Hospital Addition.—A preview open-house and tour of a new, 30-bed, $150,000 addition to Forest Hospital, a private mental institution, was

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

held Aug. 8 at the hospital, 555 Wilson Lane, Des Plaines. The tour included all the features of the 6,000 square foot addition, such as the solarium, patients' rooms, treatment and consultation rooms, nurses' rooms, and staff offices. Furnishings in the new private, double, and three-bed rooms include sofa beds, desks, lounge chairs, and original paintings to produce the appearance of lounges, rather than of hospital rooms. The present facilities of 50 beds will be increased to 90 with the new addition.

Chicago

Lecture by Uruguayan Physiologist.—Prof. Roberto Caldeyro-Barcia, chairman, section on obstetrical physiology, School of Medicine, Montevideo, Uruguay, will present "Recent Advances in our Knowledge on Oxytocin," Wednesday, Sept. 23, 4:30 p. m., at Dora De Lee Hall, The Chicago Lying-in Hospital, University of Chicago School of Medicine.

Dr. Newman Cited.—Dr. Louis B. Newman was the recipient of the 1959 "Citation for Public Service" from the University of Chicago. He was awarded the citation for having "accepted the privileges of a university education by assuming the obligations to society in exercising leadership in those civic, social, and religious activities that are essential to a democracy; for his public spirited citizenship and unselfish and effective service to the community, the nation, and humanity; and for the credit this service has reflected on the University and its alumni." Dr. Newman, chief of the physical medicine and rehabilitation service, Veterans Administration Research Hospital, is president of the American Academy of Physical Medicine and Rehabilitation.

INDIANA

Experimental Education Program.—Indiana University announced the appointment of Dr. Douglas A. MacFadyen, of the University of Illinois College of Medicine, Chicago, to direct its new experimental program in medical education to be inaugurated in September. The new program, "a departure and extension of traditional medical training," was announced early this year coincident with the university's receipt of a pilot grant of $173,000 by the Commonwealth Fund. Starting this fall with a limit of 10 students, selected from about 180 to be admitted to the School of Medicine, the program will draw on the resources of the College of Arts and Sciences and Graduate School and will be administered by the Medical School at Indianapolis under Dean John D. VanNuys. Eventually, 30 students at the end of their junior year in arts and sciences will be selected. "Students in the new program," it was explained by Dr. MacFadyen, "will accomplish work for an A.B. degree and then work in the six preclinical departments constituting the first two years of a medical curriculum and a broader than usual scientific and cultural training capped by an A.M. degree. Thereafter, each student may proceed in either of two directions, either to a medical career after a clinical training with or without further work in the Graduate School or to some other career in research and teaching." The new program has these objectives: a thorough training in polytechnical and cultural subjects, preparation of medical students whose paramount interests are in research and teaching, and an increase in the number of "broadly qualified" physicians. Dr. MacFadyen, also will be professor of pathology in the School of Medicine.

NEW JERSEY

Change of Address.—The new address of the Academy of Medicine of New Jersey is: Academy of Medicine of New Jersey, Library, 307-17 Belleville Ave., Bloomfield, N. J. The old address, no longer effective, was 91 Lincoln Park, Newark 2, N. J.

Survey of Nurses.—Rutgers University College of Nursing, in cooperation with the New Jersey Division of Civil Defense, will distribute a questionnaire in October to the state's 35,000 registered professional nurses to inventory their qualifications and locations and note shortages. The four-page survey has 46 questions. The study seeks to determine where nurses are employed, type of nursing performed, educational qualifications, psychiatric and public health nursing education and experience, degree of activity and income during 1959, specialized experience, postlicensing education and reasons for inactivity in the profession.

NEW YORK

New York City

Personal.—Dr. Irwin L. V. Norman was appointed medical director of The Chase Manhattan Bank. Dr. Norman served in the U. S. Navy from 1927 until April 30, when he retired with rank of rear admiral.——Dr. George M. Wheatley was appointed head of the Metropolitan Life Insurance Company's health and welfare division, succeeding Dr. William P. Shepard, who recently was appointed chief medical director of Metropolitan and placed in charge of all the company's medical and public health activities.

Dr. Ferree Named Director of Blindness Society.—Appointment of Dr. John W. Ferree as successor to Dr. Franklin M. Foote, former executive director of the National Society for the Prevention of Blindness, was announced by Ira V. Hiscock, Sc.D., the Society's president. For the past 11 years Dr. Ferree has been director of Community Service and Education and for two years associate medical director of the American Heart Association. Dr. Foote resigned recently to accept appointment as commissioner of the Connecticut State Department of Health, Hartford. The Connecticut health program is being expanded to include administration of four hospitals for chronic disease and two for mentally handicapped children.

Dr. Swan Named Anatomy Chairman.—The appointment of Dr. Roy Craig Swan Jr. as chairman of the department of anatomy has been announced by Cornell University Medical College. Dr. Swan from 1950-1952 was a research fellow in medicine, Harvard Medical School, and resident in medicine, Peter Bent Brigham Hospital, Boston. Since then he was an instructor, assistant, and then associate professor of physiology at Cornell University Medical College. He has been a Life Insurance Medical Research Fund Fellow and a Markle Scholar in Medical Sciences. He is a diplomate of the American Board of Internal Medicine.

Units for Heart Disease Patients.—Two new units of a program to advance Presbyterian Hospital's facilities for the diagnosis and surgical treatment of heart diseases have been completed. The program was facilitated by a research grant from the John A. Hartford Foundation, Inc., and is the result of three years planning by a group of Columbia-Presbyterian Medical Center anesthesiologists, surgeons, cardiologists, and radiologists. The cardiac special care unit is a recovery room for patients who have undergone heart surgery. The unit is staffed by nurses with experience in the postoperative care of this type of patient and fills the need of providing intensive care over a period of several days. Each of the five beds has its own battery of equipment for constant monitoring of the patient's recovery. The diagnostic unit includes a modern angiocardiography room which will more than double Presbyterian Hospital's facilities for caring for cardiac patients.

OKLAHOMA

Doctors Building Opened.—The new seven-story Doctors Building at 21st and Lewis Streets, in Tulsa, was opened in June. Erected at a cost of $1,500,000, the structure provides offices for 53 physicians and four dentists. Among the facilities in the new building are two radiology laboratories, three pathology and bacteriology laboratories, a pharmacy, optician, and coffee shop. Work on the 65,000 square foot unit which was begun 15 months ago was financed by its tenants through the self-owned Twenty-first Street Building Corporation. The building has walls of insulated procelain steel panels, with structural columns and windows covered with aluminum. It is completely air-conditioned and uses a specially engineered type of heating equipment to meet the needs of multiple examination and treatment rooms. Each suite is designed to the individual requirements of the tenant. A parking area east of the building provides parking for patients and visitors. A second lot located west, across Lewis Avenue accommodates cars of doctors and office personnel.

Dr. Turner Named Schering Scholar.—The Endocrine Society named Dr. Henry H. Turner, Oklahoma City, as this year's Schering Scholar. The award was presented to Doctor Turner during June 5 ceremonies held in conjunction with the annual meeting of the organization in Atlantic City. An anonymous committee of the Council of the society selected Dr. Turner for the $2,500 grant on the basis of his accomplishments as an established investigator in the fields of endocrinology. The cash award is made possible by the Schering Corporation and is presented annually to a "deserving physician who wishes to extend the opportunities for his work either here or abroad." Dr. Turner has announced that he intends to utilize the grant by attending both the 1960 International Goiter Conference, London, and the International Congress of Endocrinology, to be held in Copenhagen the same year. While abroad, he will also visit with a number of European investigators. In addition to being the Schering Scholar, he holds the office of secretary-treasurer for the national organization and is president of the National Society of Nuclear Medicine.

OREGON

Meeting on General Practice in Portland.—The Oregon Academy of General Practice will present "Horse and Buggy Doctor" as the 12th annual scientific session of the Northwest Regional Academy meeting, Sept. 9-11, at the Portland State College, Portland. Dr. Howard A. Rusk, chairman, department of physical medicine and rehabilitation, New York University-Bellevue Medical Center, and Dr. Edward H. Rynearson, chairman, section on metabolic diseases, Mayo Clinic, Rochester, *Minn.*, will be the Sommer Memorial Lecturers. Other speakers include the following: Drs. A. Cannon Eley, Boston; L. Henry Garland, San Francisco; Ian MacDonald, Los Angeles; John O. McCall Jr., Portland; Leland S. McKittrick, Brookline, Mass.; Frank W. Norman, Santa Rosa, Calif.; Richard H. Overholt, Boston; Robert H. Tinker, Portland; and Roger H. L. Wilson, San Francisco. At the annual banquet Sept. 10, 7:30 p. m., Dr. Fount Richardson, Fayetteville, Ark., president, American Academy of General Practice, will be the speaker. Exhibits are planned, and entertainment includes a cruise and deep-sea fishing. The program has been approved for 15 hours of category I credit. There is no registration fee. The theme "Horse and Buggy Doctor," was selected to celebrate Oregon's 100th birthday as a state. For information write Mrs. Thomas Sterm, Chairman, Advance Registration Committee, Route 4, Sherwood, Ore.

PENNSYLVANIA

Philadelphia

Dr. Koprowski Awarded Alvarenga Prize.—On July 14, the College of Physicians of Philadelphia awarded the Alvarenga Prize for 1959 to Dr. Hilary Koprowski, professor of research medicine, University of Pennsylvania, "for his outstanding work on the development of a living attenuated virus vaccine against poliomyelitis." The Alvarenga Prize was established by the will of Pedro Francisco DaCosta Alvarenga, of Lisbon, Portugal, an associate fellow of the College of Physicians of Philadelphia, to be awarded annually by the college on the anniversary of the death of the testator, July 14, 1883.

Personal.—At the 60th annual meeting of the American Gastroenterological Association Dr. Russell S. Boles was presented with the Julius Friedenwald Medal, awarded each year to a member of the association "for outstanding achievement in gastroenterology." ——Dr. Gordon N. French, of Brookline, Mass., was appointed director of internal medicine at Misericordia Hospital. Dr. French was formerly on the faculty of medicine at Tufts University Medical School and a research associate in physiology at Harvard School of Public Health.

Teaching and Research Center.—The development of a new integrated teaching and research center for the basic biological sciences at the University of Pennsylvania, to be closely associated with the university's School of Medicine, was made possible by three grants totaling $1,903,345. Grants of $1,000,000 from the Longwood Foundation, a philanthropic organization created by Pierre S. duPont; $473,345 from the U. S. Public Health Service; and $430,000 from the Rockefeller Foundation will bring into being a new building for the university's division of biology, directed by David R. Goddard, Ph.D., Gustave C. Kuemmerle Professor of Botany. Several levels will interconnect with the Medical School's research building. The grants also make possible rehabilitation of portions of an existing zoology building, to which the new structure will be joined, and provide construction of greenhouses and a service laboratory. The building will be adjacent to the School of Medicine's new medical research building under construction on Hamilton Walk. The new air-conditioned biology building will be about 36,000 square feet in area and will include lecture and seminar rooms, a biological library, teaching laboratories, and research rooms. The new 4,000-square-foot service laboratory, which will connect with the remodeled zoology building, will contain air-conditioned animal quarters and climatically and atmospherically controlled experimental plant growth chambers. Construction of the biology building, renovation of the zoology building, and construction of the adjacent structures will accomplish the university's goal of physical integration of the division of biology. The division was organized in 1957 through academic and administrative integration of the earlier departments of botany, zoology, and microbiology of the College of Arts and Sciences.

SOUTH CAROLINA

Hospital Dedicated in Charleston.—Dedication ceremonies for the new McClennan-Banks Memorial Hospital on Courtenay Drive, Charleston, were held on May 31. The 31-bed hospital, which cost $686,000 in county and federal funds, is now open for patients. It has one private room, 11 two-bed rooms, and two four-bed wards and a conference room. Dr. Thomas C. McFall, administrator of the new hospital, has been a leader in efforts to establish a new unit as a replacement for the old Negro Hospital and Training School on Cannon Street. The hospital is named in honor of Dr. Alonzo Clifton McClennan and Mrs. Anna D. Banks. Dr. McClennan helped found the old Negro center and served as its medical director and surgeon until his death in 1912. He was a native of Columbia and a graduate of Howard University schools of pharmacy and medicine. Mrs. Banks was the first head nurse of the old Hospital and Training School and later became superintendent of nurses. She died in 1930.

TEXAS

Dr. May Owen Honored.—Dr. May Owen of Fort Worth, Texas, was elected president-elect of the Texas Medical Association. She will be the first woman to hold the office of president in the association's 106-year history. Dr. Owen was the first woman president of the Tarrant County Medical Society and is a past-president of the Texas Society of Pathologists.

UTAH

Annual Scientific Session.—The 64th annual scientific session of the Utah State Medical Association will be held Sept. 16-18 at the Hotel Utah Motor Lodge, Salt Lake City. Dr. Ulrich R. Bryner, Salt Lake City, president of the association will open the session with an address. Two symposiums are planned: "Newer Adrenocorticosteroids," moderated by Dr. Frank H. Tyler, and "Basic Principles and Care of Hand Injuries," moderated by Dr. Thomas R. Broadbent. The program will include papers by the following out-of-state speakers: Drs. Edward L. Bortz, Philadelphia; Thomas McPherson Brown, Washington, D. C.; Charles R. Stephen, Durham, N. C.; James R. Willson, Philadelphia; Phillips Thygeson, San Jose, Calif.; James W. Littler, New York City; John L. Emmett, Rochester, Minn.; and Reginald H. Smithwick, Boston. An informal panel discussion moderated by Dr. John F. Waldo, president, Salt Lake County Medical Society, is planned for the luncheon of Sept. 16. Specialty group discussions will be held the evening of Sept. 17. Dr. Louis M. Orr, Orlando, Fla., President, American Medical Association, will be the speaker at the president's banquet, 7:30 p. m., Sept. 18, presenting, "Medicine Is Not Failing America." For information write Mr. H. Bowman, 42 S. 5th East, Salt Lake City, Executive-Secretary.

WASHINGTON

Annual Convention in Seattle.—The 70th annual session of the Washington State Medical Association will be held Sept. 13-16, at the Olympic Hotel, Seattle. Dr. E. Vincent Askey, Los Angeles, President-Elect, American Medical Association, will be the featured speaker in the nonscientific program of the convention. Guest scientific speakers are: Drs. Lawson Wilkins, Baltimore; Carleton Mathewson Jr., San Francisco; John Shea, Memphis, Tenn.; Robert H. Williams, Seattle; and Frank C. Winter, Palo Alto, Calif. There will be Monday and Tuesday morning sessions with special subject matter in the following fields: pediatrics; internal medicine; ear, nose, and throat; surgery; and eye. General scientific sessions will be held in the afternoon. The scientific program will climax with a general scientific session the morning of Sept. 16 and a limited attendance seminar, "Electrolyte and Fluid Management Problems." President of the association is Dr. Emmett L. Calhoun of Aberdeen. For information, write Mr. Ralph W. Neill, 1309 Seventh Ave., Seattle 1, Executive Secretary.

GENERAL

Psychosomatic Meeting in Cleveland.—The sixth annual meeting of the Academy of Psychosomatic Medicine will be held Oct. 15-17, at the Sheraton–Cleveland Hotel, Cleveland. The meeting will be oriented and directed to fit the needs of nonpsychiatric physicians. Practical everyday office management of psychosomatic problems and emotional disturbances will be dealt with in formal papers, symposiums, panel discussions, and small study groups. The meeting will be open to all scientific disciplines, as well as psychologists, social workers, and nurses. Information may be obtained from Dr. Bertram B. Moss, Suite 1035, 55 E. Washington St., Chicago 2.

Society News.—At the 70th annual meeting of the **American Dermatological Association, Inc.**, in Atlantic City, Dr. Marion B. Sulzberger, of New York City, was elected president for the coming year, and Dr. Lawrence G. Beinhauer, of Pittsburgh, vice-president. Dr. Carl T. Nelson, of New York City, is treasurer, and Dr. Wiley M. Sams of Miami, Fla., secretary. The next annual meeting of the association will be held at the Boca Raton Hotel and Club, Boca Raton, Fla., April 8-12, 1960. —The officers of the **American Proctologic Society** for the year 1959-1960 are: president, Dr. Hyrum R. Reichman, Salt Lake City; president-elect, Dr. Walter A. Fansler, Minneapolis; vice-president, Dr. Neil W. Swinton, Boston; secretary, Dr. Norman D. Nigro, Detroit; and treasurer, Dr. Robert J. Rowe, Dallas, Texas. The next annual meeting will be held April 25-27, 1960, at the Shamrock Hilton Hotel in Houston, Texas.

Mississippi Valley Meeting.—The 24th annual meeting of the Mississippi Valley Medical Society will be held at the Chase Hotel, St. Louis, Sept. 29-Oct. 1, under the presidency of Dr. Arthur F. Fritchen, of Decorah, Iowa. The morning and afternoon sessions on Sept. 29 will be devoted to clinics held in the teaching hospitals of St. Louis and Washington University schools of medicine. A joint meeting with the St. Louis Academy of General Practice and the St. Louis Dental Society will be held the evening of Sept. 29, with the opening of the industrial and scientific exhibits at 6:00 p. m. on that day. Over 30 clinical teachers are on the program. In addition, the program includes Dr. Jacob A. Bargen, Rochester, Minn.; Dr. Lester R. Dragsredt, Chicago; Dr. E. Grey Dimond, Kansas City, Kan.; Dr. J. P. Greenhill, Chicago; Dr. Heyworth N. Sanford, Chicago; and Dr. Robert L. Jackson, Columbia, Mo.; Dr. Harvey Flack of London, England, will be the banquet speaker. There will be panel discussions on pediatric heart problems, surgery in peptic ulcer, heart disease and atherosclerosis, and highway injuries. A complete program may be obtained from Dr. Harold Swanberg, Secretary, W.C.U. Bldg., Quincy, Ill. (The meeting will be followed by the 16th annual meeting of the American Medical Writers' Association at the Chase Hotel, Oct. 2-3.)

Rocky Mountain Medical Conference.—On Sept. 8-11, at the Shirley–Savoy Hotel, Denver, the 10th biennial Rocky Mountain Medical Conference will be held in combination with the 89th annual session of the Colorado State Medical Society. The conference is a joint enterprise of the Colorado, Montana, New Mexico, Utah, and Wyoming state medical societies. Guest speakers at the conference are as follows: Drs. Edward L. Bortz, Philadelphia; Harold W. Dargeon, New York; Fred C. D. Collier, Birmingham, Ala.; M. Edward Davis, Chicago; L. Henry Garland, San Francisco; L. Stanley James, New York; Theodore G. Klumpp, New York; Ben M. Peckham, Madison, Wis.; Jack Weinberg, Chicago; and Danely P. Slaughter, Chicago. Three closed circuit television clinics are planned: "Ob-Gyn and Pediatrics," "Leukemias and Lymphomas," and "Care and Rehabilitation of the Older Patient." Scientific and technical exhibits are planned. A program of entertainment and special events is arranged. A banquet will be held Sept. 10, at 7:30 p. m. Registration fee is $5. For information write Mr. Harvey T. Sethman, Executive Secretary, Colorado State Medical Society, 835 Republic Building, Denver 2.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Care of Child with Rheumatic Fever.—A new booklet, "Home Care of the Child with Rheumatic Fever," was published by the American Heart Association and its affiliates. The booklet was prepared especially for parents of children who have rheumatic fever or are recovering from it and for whom hospital care is either not advised or not available. Copies may be requested by physicians and others from local heart associations to give to parents of rheumatic fever patients. The 24-page illustrated booklet gives details about the role of the mother in caring for the sick child and the importance of following the regimen prescribed by the physician. Instruction is included on bathing the child in bed, giving medicine, taking the pulse and temperature, and keeping records.

Red Cross Adopts Mouth-To-Mouth Lifesaving Method.—The American Red Cross officially adopted the mouth-to-mouth technique of artificial respiration for adults as well as children. Teaching of the method in Red Cross first aid and water safety courses will begin immediately. The technique was declared the most practical in a unanimous verdict of a committee of the National Academy of Sciences—National Research Council after a thorough review of artificial respiration data. The Red Cross delayed announcement of its adoption of the method only long enough to prepare and have published an instruction manual for use of its volunteer class instructors. Distribution of copies of this manual to the 3,700 Red Cross Chapters was completed early in July. The Red Cross still considers manual methods of artificial respiration acceptable for rescuers who cannot or will not use the mouth-to-mouth or mouth-to-nose technique. The two methods it recommends are the Nielsen back pressure-arm lift method and the Silvester chest pressure-arm lift method.

LATIN AMERICA

Research in Genetics by Brazilian Scientists.—Four Brazilian universities and the Brazilian Society of Genetics are cooperating in a major new program of research in human genetics with the help of five Rockefeller Foundation grants totaling $120,250. Brazilian geneticists have already made distinguished collaborative research on Drosophila population genetics. Their new cooperative program in human genetics will be planned primarily by the Brazilian Society of Genetics. The University of São Paulo is the first Brazilian school to offer a course in human genetics to medical students, and the first to develop a broad research program in the field. Research in human genetics already in progress at the University of Paraná, Curitiba, includes a study of consanguineous marriages in several Brazilian states. The University of Rio Grande do Sul, in Porto Alegre, will establish a human serum bank where antisera will be available to all investigators. Genetic studies on several Indian tribes, including one in an isolated region of the Amazon Basin, will be done by the University of Bahia in Salvador.

CORRECTION

Polyps of the Colon and Rectum.—In the article "Polyps of the Colon and Rectum" by Rider et al. (in THE JOURNAL, June 6, page 633) the term adenocarcinoma was used throughout in place of the term adenoma malignum, to agree with the terminology preferred in the fourth edition of Standard Nomenclature of Diseases and Operations. The authors have now stated that throughout their paper the meaning of adenocarcinoma is adenocarcinoma grade 1, or the synonyms adenocarcinoma in situ or adenoma malignum.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Various Centers: Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates: Stations around the world, Sept. 22. Final date for filing applications was June 22. Succeeding examinations—March 16, 1960 and Sept. 21, 1960. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 21-23, 1960. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery.

Alaska:* On application in Anchorage or Fairbanks. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Examination.* Phoenix, Oct. 14-16. *Reciprocity.* Phoenix, Oct. 17. Ex. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, Nov. 5-6. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* Sacramento, October 19-22. *Oral.* Los Angeles, August 15; San Francisco, November 14. *Oral and Clinical.* Los Angeles, August 16; San Francisco, Nov. 15. Sec., Dr. Louis E. Jones, Room 536, 1020 N Street, Sacramento.

Connecticut:* *Homeopathic. Examination.* Derby, Sept. 8. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

District of Columbia:* *Examination.* Washington, Dec. 14-15. *Reciprocity.* Washington, Sept. 14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., Washington 6.

Florida:* *Examination.* Miami Beach, Nov. 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, Oct. 13. Sec., Mr. Cecil L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Indiana: *Examination.* Indianapolis, June 1960. *Reciprocity.* Indianapolis, fourth Wednesday of each month. Ex. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Kansas:* *Examination and Reciprocity.* Kansas City, January 1960. Sec., Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

Louisiana: *Examination and Reciprocity.* New Orleans, Dec. 3-5. Sec., Dr. Edwin H. Lawson, 930 Hibernia Bank Bldg., New Orleans 12.

Maryland: *Examination.* Baltimore, Dec. 8-11, Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore 1.

Minnesota:* *Examination and Reciprocity.* St. Paul, Oct. 20-22. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 2.

Montana: *Examination and Reciprocity.* Helena, Oct. 6. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination.* Omaha, June 13-15, 1960. Dir., Bureau of Examining Boards, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada:* *Examination and Reciprocity.* Reno, Sept. 8. Sec., Dr. G. H. Ross, 112 North Curry St., Carson City.

New Hampshire: *Examination and Reciprocity.* Concord, Sept. 9-12. Sec., Dr. Edward W. Colby, 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 20-23, *Reciprocity.* Monthly, Sec., Dr. Royal A. Schaaf, 28 West State St., Trenton.

New Mexico:* *Examination and Reciprocity.* Santa Fe, Nov. 16-17. Sec., Dr. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, Dec. 8-11. Sec., Dr. Stiles D. Ezell, 23 South Pearl St., Albany.

Ohio: *Examination.* Columbus, Dec. 15-17. *Endorsement.* Columbus, Aug. 26 and Oct. 5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oregon:* *Examination.* Portland, Oct. 22-24. Ex. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Puerto Rico: *Examination.* San Juan, Sept. 8. Sec., Dr. Joaquin Mercado Cruz, Box 9156, Santurce.

South Dakota:* *Examination.* Sioux Falls, Aug. 25-26. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination.* Memphis, Sept. 23-24. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Texas:* *Examination.* Fort Worth, Dec. 3-5. *Reciprocity.* Houston, Aug. 29-31. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Virginia: *Examination and Reciprocity.* Richmond, Dec. 2-4. Address: Board of Medical Examiners, 631 First St. S.W., Roanoke.

Wyoming: *Examination and Reciprocity.* Cheyenne, Oct. 5. Sec., Dr. James W. Sampson, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: *Examination and Reciprocity.* Juneau, November. Sec., Dr. R. Harrison Leer, Alaska Office Bldg., Juneau.

Arizona: *Examination.* Tucson, Sept. 15. Sec., Mr. Herman E. Bateman, University of Arizona, Tucson.

Colorado: *Examination.* Denver, Sept. 2-3. *Reciprocity.* Denver, Sept. 4. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: *Examination.* New Haven, Oct. 10. Exec. Asst., Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

District of Columbia: *Examination.* Washington, Nov. 23-24. *Reciprocity.* Washington, Sept. 14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., Washington 6.

Kansas: *Examination.* Pittsburg, Nov. 6-7. Sec., Dr. Leon C. Heckert, Kansas State College, Pittsburg.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 9-10. Sec., Mrs. Anne Baker, West Michigan Ave., 116 Stevens T. Mason Bldg., Lansing.

Minnesota: *Examination.* Minneapolis, Oct. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Nevada: *Reciprocity*, Sept. 8. Sec., Dr. Kenneth C. Kemp, Box 9355, University of Nevada, Reno.

New Mexico: *Reciprocity.* Santa Fe, Oct. 7. Sec., Mrs. M. Cantrell, P. O. Box 1522, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, Sept. 25-26. Exec. Sec., Mrs. L. Haidek, 813 Braniff Bldg., Oklahoma City.

South Dakota: *Examination.* Vermillion, Dec. 4-5. Dr. Gregg M. Evans, 310 East 15th St., Yankton.

Texas: *Examination.* Austin, Oct. 12-13. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 11 and Milwaukee, Dec. 5, Sec., Mr. Wm. H. Barber, 621 Ranson St., Milwaukee.

---

*Basic Science Certificate required.

GOVERNMENT SERVICES

ARMY

Dr. Sim Honored.—Dr. Van M. Sim, chief of the Chemical Warfare Laboratories' clinical research division at Army Chemical Center, Maryland, was given the Army's highest civilian award, the Decoration for Exceptional Civilian Service. Dr. Sim was cited for "volunteering to be the first to expose himself to several new chemical agents at the risk of grave personal injury and the direction of a program whereby over 400 volunteers have been exposed without a single injury."

Personal.—Col. James T. McGibony, M. C., was appointed chief of the medical plans and operations division in the office of the surgeon general thereby succeeding Col. Angel A. Cardona, M. C., who is now surgeon of the military district of Washington.

NAVY

Personal.—Capt. Clifford P. Phoebus, M.C., U. S. Navy, recently reported to the Bureau of Medicine and Surgery for duty as director, Astronautical Division.

VETERANS ADMINISTRATION

Personal.—Dr. Frederick J. Rachiele, formerly director of professional services at the Veterans Administration hospital in Denver, Colo., wa appointed manager of the Tucson, Ariz., VA hospital.

PUBLIC HEALTH SERVICE

Directory of Research Fellows.—The National Cancer Institute has published the first directory of its research fellows since the fellowship program was established in 1937. Section 1 of the directory contains the names of 924 persons whose fellowships were completed prior to April 1, 1958, and section 2 contains the names of 245 persons whose fellowships extended beyond that date. A brief statement about each fellow tells the highest degree he held at the time of his appointment, the name of the school granting the degree, the type, duration, and place of his fellowship, and the name of the research project. The present position of those whose fellowships had terminated by April 1, 1958, is also given. The introduction to the directory discusses the history of the program, which was the first of its kind to be supported by the federal government.

Most of the former fellows are now engaged in research or teaching or both. About half of the fellows appointed in the early years of the institute are now permanent members of the institute's staff in key research positions, and a number of the later fellows have also joined the staff. Copies of the directory (Research Fellows of the National Cancer Institute, 1938-1958) were sent to the libraries of appropriate institutions, including four-year colleges, medical schools, and foundations supporting research. Copies are also on sale by the Superintendent of Documents, Government Printing Office, Washington 25, D. C., for 45 cents a copy.

Appointments to Selection Committee for Senior Research Fellowships.—Drs. Kimball C. Atwood, of the department of obstetrics and gynecology at the University of Chicago; Howard C. Hopps, chairman of the pathology department at the University of Texas; Eli D. Goldsmith, professor of histology and research coordinator at New York University College of Dentistry; Antonio Ciocco, head of the department of biostatistics at the University of Pittsburgh's Graduate School of Public Health; and John B. Graham, professor of pathology at the University of North Carolina, were appointed to serve three-year terms on the selection committee for the Senior Research Fellowship program of the National Institutes of Health. They will advise and make recommendations to the surgeon general on the selection of qualified persons for the five-year fellowships. The fellowship awards are designed principally for promising young scientists sponsored by preclinical departments in the period between the completion of their postdoctoral research training and their eligibility for permanent higher academic appointments. Under special circumstances, senior scientists may be awarded these fellowships to supply needed strength in preclinical science departments.

Personal.—Dr. Henry S. Kaplan, professor of radiology at Stanford University School of Medicine, and Dr. Stanhope Bayne-Jones, well-known medical educator, were appointed to four-year terms as members of the National Advisory Cancer Council, effective Oct. 1. In this capacity they will advise and make recommendations to the surgeon general regarding research activities of the National Cancer Institute. The council is composed of 12 members, 6 of whom are leaders in science and 6 leaders in education and public affairs.

FEDERAL AVIATION AGENCY

Civil Air Surgeon Appointed.—Dr. James L. Goddard was appointed civil air surgeon of the Federal Aviation Agency. He is the first to hold this title, although the post had been filled on an acting basis by Dr. John E. Smith. Dr. Smith is now chief of the research requirements in the office of the civil air surgeon. The civil air surgeon is concerned with the mental and physical fitness of airmen and air traffic controllers and the chief of the research requirements division is responsible for the application of findings of aeromedical research to civil aviation.

DEATHS

Bauer, Wesley Warren Ⓜ Fort Morgan, Colo.; (licensed in Colorado in 1920); died May 31, aged 64.

Benson, Theodore J. Ⓜ Fromborg, Mont.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1904; served as mayor and member of the school board; died in the Deaconess Hospital, Billings, June 2, aged 85.

Bronson, Malcolm Ⓜ Hamilton, Ohio; Miami Medical College, Cincinnati, 1908; died May 31, aged 74.

Buckingham, Edwin Wheeler II Ⓜ Newport News, Va.; Medical College of Virginia, Richmond, 1918; veteran of World War I; served as a medical missionary in China; associated with the Riverside Hospital, where he was secretary-treasurer of the medical staff from 1931 to 1947; recently honored as the city's Doctor of the Year; died June 6, aged 66.

Canright, Harry Lee, St. Cloud, Fla.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; for many years a medical missionary in China; died May 28, aged 94.

Clauser, Eldo Horace Mann Ⓜ Muncie, Ind.; born in Owasco, Ind., March 27, 1890; Indiana University School of Medicine, Indianapolis, 1915; past-president and charter member of the Muncie Academy of Medicine; past-president of the Delaware–Blackford Counties Medical Society; fellow of the American College of Surgeons, of which he was a member of the board of governors from 1955 to 1958, and a past-president of the Indiana Chapter; served as chairman of the executive committee and member of the council of the Indiana State Medical Association; founding member of the U. S. Committee of the World Medical Association; since its inception, chairman of the Indiana Hospital Licensing Committee; veteran of World War I; a member of the board of governors of the Blue Shield; a member of the board of directors of the local YMCA; past-president of the Muncie Kiwanis Club and the local Indiana University Alumni Association; for many years chairman of the executive committee of the staff of Ball Hospital, where he died May 31, aged 69.

Cooney, M. Blanche Ⓜ West Newbury, Mass.; Tufts College Medical School, Boston, 1911; served on the staff of the Hale Hospital in Haverhill; died May 23, aged 69.

Culbertson, Ora J. Ⓜ Belleville, Ill.; St. Louis University School of Medicine, 1902; fellow of the American College of Surgeons; associated with the St. Mary's and Christian Welfare hospitals; died May 29, aged 81.

Driskell, Cecil Rogers Ⓜ Springfield, Ill.; St. Louis University School of Medicine, 1906; past-president of the Montgomery County Tuberculosis Association; died in St. John's Hospital May 20, aged 74.

Gallagher, James S. Ⓜ St. Petersburg, Fla.; Temple University School of Medicine, Philadelphia, 1909; for many years practiced in Philadelphia; died in the Episcopal Hospital, Philadelphia, June 4, aged 74.

Gallaspy, Glenn Todd Ⓜ West Monroe, La.; Emory University School of Medicine, Atlanta, 1931; associated with St. Francis Hospital in Monroe, where he died May 30, aged 51.

Gerstner, David, Kansas City, Mo.; Eclectic Medical University, Kansas City, 1918; died May 28, aged 80.

Ghormley, Ralph Kalb Ⓜ Carmel, Calif.; born in Portland, Ore., Feb. 10, 1893; Johns Hopkins University School of Medicine, Baltimore, 1918; following service as a medical officer with the American Expeditionary Forces, interned at Johns Hopkins Hospital and Children's Hospital in Baltimore and the New York Hospital in New York City; in 1921-1922 assistant resident surgeon at Johns Hopkins Hospital in Baltimore; entered the practice of orthopedic surgery in Boston, where in 1922-1923 he was an assistant in orthopedic surgery at Harvard Medical School, and later an instructor; served as attending orthopedic surgeon to the Massachusetts General Hospital in Boston; came to Rochester, Minn., in September, 1929, as a consultant in orthopedic surgery at the Mayo Clinic and assistant professor in Mayo Foundation, Graduate School, University of Minnesota; advanced to associate professor in 1932 and full professor in 1937 and, in 1938, became head of the orthopedic section of the Mayo Clinic, a post he held until 1955, when he became a senior consultant; specialist certified by the American Board of Orthopedic Surgery, of which he was past-president; past-president and secretary of the American Orthopedic Association; past-president of the Clinical Orthopaedic Society; elected president of the staff of the Mayo Clinic in 1952 and served as president of the Mayo Foundation Chapter of the Society of the Sigma Xi in 1943-1944; member of the Western Surgical Association, American Academy of Orthopedic Surgeons, American Association for the Sur-

gery of Trauma, the Robert Jones Orthopedic Society, International Society of Orthopedic Surgery and Traumatology, the Alpha Omega medical honor society, the Harvard Club of Boston, and the Alumni Association of the Mayo Foundation; a corresponding member of the Scandinavian Orthopedic Society; fellow of the American College of Surgeons; in 1954 received a certificate of merit from the American Medical Association for an exhibit on Primary Tumors of the Soft Tissues of the Extremities Exclusive of Epithelial Tumors—An Analysis of 500 Consecutive Cases and in 1956 received a certificate of merit for exhibit on Bone Tumors; served on the staffs of the St. Mary's and Colonial hospitals in Rochester, Minn.; a consultant in his specialty to the U. S. Veterans Administration; served as a member of the advisory committee of the Children's Bureau of the U. S. Department of Labor; in 1942 gave the William J. Mayo Clinic Lecture at the University of Michigan in Ann Arbor; in 1957 was honored by former fellows in orthopedic surgery of the Mayo Foundation and colleagues at the Mayo Clinic with the establishment of the Ralph K. Ghormley Traveling Scholarship; joint author of "Diagnosis in Joint Disease: a Clinical and Pathologic Study of Arthritis"; editor of a volume "Orthopedic Surgery" published in 1938; associated with Monterey (Calif.) Hospital and the Peninsula Community Hospital, where he died June 6, aged 66.

Glasener, Charles F., Bradenton, Fla.; Loyola University School of Medicine, Chicago, 1916; for many years on the staff of the Elmhurst (Ill.) Community Hospital; died in the Manatee Veterans Memorial Hospital May 28, aged 76.

Glickman, Abraham Jacob Ⓜ Boston; University of St. Vladimira Faculty of Medicine, Kiev, Russia, 1904; died April 27, aged 80.

Greer, Charles Edward Ⓜ Charleston, Ill.; Chicago Homeopathic Medical College, 1898; veteran of World War I; member of the honorary staff of the Charleston Community Memorial Hospital, where he died June 1, aged 84.

Griffin, Silas Ⓜ St. Petersburg, Fla.; Kentucky University Medical Department, Louisville, 1900; for many years practiced in Henderson, Ky.; served as secretary of the Henderson County (Ky.) Medical Society and health officer of Henderson County; died in St. Anthony Hospital May 25, aged 83.

Hahn, Charles David, Baltimore; Medical College of Ohio, Cincinnati, 1897; died June 4, aged 86.

Hanley, James Leo Ⓜ Bridgeport, Conn.; Yale University School of Medicine, New Haven, 1935; certified by the National Board of Medical Examiners; interned at University Hospitals in Cleveland; served a residency at the Woman's Hospital in Detroit; formerly a fellow at the Mayo Foundation in Rochester, Minn.; veteran of World War II; associated with Bridgeport Hospital and St. Vincent's Hospital, where he died May 31, aged 49.

Harris, Abraham J. Ⓜ Newton, Mass.; Mid-West Medical College, Kansas City, Mo., 1934; died May 30, aged 66.

Hathaway, Alfred H. Ⓜ Mountain View, Okla.; University of Arkansas School of Medicine, Little Rock, 1905; died May 25, aged 87.

Heitmann, Kenneth Arnold Conrad Ⓜ Santa Ana, Calif.; University of Michigan Medical School, Ann Arbor, 1935; specialist certified by the American Board of Radiology, Inc.; member of the American College of Radiology; died May 26, aged 49.

Hickman, John Samuel Ⓜ Meridian, Miss.; Mississippi Medical College, Meridian, 1911; served as a member of the state legislature; for many years superintendent of the East Mississippi Hospital; died in the Rush Memorial Hospital May 31, aged 75.

Holt, Robert Edward Lee, Portland, Ore.; University of Oregon Medical School, Portland, 1908; served on the staff of the Providence Hospital, where he died June 1, aged 78.

Kass, Paul, Miami Beach, Fla.; University of Virginia Department of Medicine, Charlottesville, 1928; died in North Miami May 26, aged 56.

Kitchens, Orren William Ⓜ Byromville, Ga.; Atlanta Medical College, 1915; vice-chairman of the Dooly County Board of Commissioners; member of the city council for 42 years; on the staff of the Riverside Hospital in Montezuma; a director of the Byromville Bank; died in the Montezuma (Ga.) Hospital June 1, aged 67.

Koll, Irvin Sunthimer, Beverly Hills, Calif.; Rush Medical College, Chicago, 1907; specialist certified by the American Board of Urology; member of the American Urological Association; formerly practiced in Chicago, where he was associated with the Michael Reese Hospital, where in 1956 he was awarded a bronze plaque for at least 30 years service; author of "How to Stay Healthy"; died May 30, aged 75.

Kuykendall, Pere Moran Ⓜ Ranger, Texas; Baylor University College of Medicine, Dallas, 1917; past-president of the Eastland County Medical Society; veteran of World War I; served as medical director of the West Texas Hospital; past-president of the Chamber of Commerce, Eastland County Water Board, and Rotary Club; served as a member and president of the Eastland County School Board; died in the Ranger General Hospital May 28, aged 66.

Lang, Charles Albert, New York City; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1898; retired assistant attending in pediatrics at the Presbyterian Hospital, where he died June 1, aged 83.

Leach, Charles Henry Ⓜ Tenants Harbor, Maine; Medical School of Maine, Portland, 1899; died in Rockland May 25, aged 85.

Levy, Simon Cuthbert, Plaquemine, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1897; associated with the Plaquemine Sanitarium, where he died June 1, aged 86.

Linsin, Ivan M., St. Petersburg, Fla.; Bennett Medical College, Chicago, 1910; formerly associated with the Indian Service; died in Tampa May 29, aged 72.

Luce, Rey Vincent Ⓜ Santa Rosa, Calif.; Rush Medical College, Chicago, 1913; fellow of the American College of Surgeons; veteran of World War I; formerly practiced in Akron, Ohio, where he was chief of staff at Akron City Hospital; past-president of the Summit County (Ohio) Medical Society; died in Boyes Springs, May 30, aged 71.

Marchman, Oscar Milton Ⓜ Dallas, Texas; born in Jefferson, Texas, April 5, 1872; Missouri Medical College, St. Louis, 1899; also a pharmacist; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served as secretary of the Texas Ophthalmological and Otolaryngological Society; first president of the Dallas Academy of Medicine, which he helped organize; past-president of the Dallas Southern Clinical Society and the Dallas Academy of Ophthalmology and Otolaryngology; oldest active member of the Dallas County Medical Society, of which he was past-president, was recently given the "Golden Deeds" award by the Dallas Exchange Club for his "unselfish service"; emeritus professor of otolaryngology, Southwestern Medical School of the University of Texas; formerly on the faculty of the Baylor University College of Medicine; at one time secretary of the city board of health; past-president of the Dallas chapter of the American Red Cross; helped organize the Dallas Health and Science Museum, of which he was a trustee; associated with the Baylor University Hospital, Medical Arts Hospital, and Children's Medical Center; died in the Baylor University Hospital May 25, aged 87.

Mathers, James Andrew, Kingston, N. Y.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1917; veteran of World War I; member of the staffs of the Kingston and Benedictine hospitals; died May 19, aged 65.

Matthews, Charles B. Ⓜ Hammond, Ind.; Kentucky School of Medicine, Louisville, 1894; veteran of World War I; associated with St. Margaret Hospital; died May 30, aged 86.

Nicholls, James Benton Ⓜ Windsor, N. C.; University of Maryland School of Medicine, Baltimore, 1910; member of the American Trudeau Society; in February, 1953, a new building at the Catawba Sanatorium was named in his honor and later that year he retired as superintendent and medical director, after many years of service; died May 15, aged 71.

Noe, Carl Abraham Ⓜ Cedar Rapids, Iowa; State University of Iowa College of Medicine, Iowa City, 1929; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology; served as secretary treasurer of the Iowa Academy of Ophthalmology and Otolaryngology; veteran of World War II; associated with Methodist Hospital, St. Luke's Hospital, where he was president-elect of the staff, and the Mercy Hospital, where he died May 26, aged 54.

Philp-Bradshaw, Martha, San Francisco; Dalhousie University Faculty of Medicine, Halifax, N. S., Canada, 1902; for many years a medical missionary in China; died May 29, aged 89.

Powell, Eppie Clifton, Middlesex, N. C.; University of Nashville (Tenn.) Medical Department, 1907; chairman of the Nash County Board of Health and Middlesex School Board; for many years physician to the Free Will Baptist Orphanage; a director of Peoples Bank & Trust Company; past-president of the Middlesex Rotary Club; died in the Wayne Memorial Hospital, Goldsboro, May 26, aged 75.

Ray, Fred Merton Ⓜ Pocatello, Idaho; Northwestern University Medical School, Chicago, 1909; veteran of World War I; associated with St. Anthony Hospital and Bannock Memorial Hospital, where he died May 29, aged 77.

Roark, Jesse Lawrence, Albuquerque, N. M.; born in Water Valley, Miss., Sept. 30, 1895; Jefferson Medical College of Philadelphia, 1924; served overseas during World War I; interned at the Jefferson Medical College Hospital in Philadelphia and served a residency at the White Haven Sanitorium in White Haven, Pa.; at one time on the teaching staff of his alma mater; formerly medical director of Lafayette and Yalobusha counties in Mississippi; served on the staffs of the Mississippi State Sanatorium for Tuberculosis in Sanatorium, Pennsylvania State Sanatorium for Tuberculosis in South Mountain, Pa., Essex County Sanatorium for Tubercular Diseases in Verona, N. J., and the Arkansas gery of Trauma, the Robert Jones Orthopedic Society, International Society of Orthopedic Surgery and Traumatology, the Alpha Omega medical honor society, the Harvard Club of Boston, and the Alumni Association of the Mayo Foundation; a corresponding member of the Scandinavian Orthopedic Society; fellow of the American College of Surgeons; in 1954 received a certificate of merit from the American Medical Association for an exhibit on Primary Tumors of the Soft Tissues of the Extremities Exclusive of Epithelial Tumors—An Analysis of 500 Consecutive Cases and in 1956 received a certificate of merit for exhibit on Bone Tumors; served on the staffs of the St. Mary's and Colonial hospitals in Rochester, Minn.; a consultant in his specialty to the U. Ray, Fred Merton Ⓜ Pocatello, Idaho; Northwestern University Medical School, Chicago, 1909; veteran of World War I; associated with St. Anthony Hospital and Bannock Memorial Hospital, where he died May 29, aged 77.

Roark, Jesse Lawrence, Albuquerque, N. M.; born in Water Valley, Miss., Sept. 30, 1895; Jefferson Medical College of Philadelphia, 1924; served overseas during World War I; interned at the Jefferson Medical College Hospital in Philadelphia and served a residency at the White Haven Sanitorium in White Haven, Pa.; at one time on the teaching staff of his alma mater; formerly medical director of Lafayette and Yalobusha counties in Mississippi; served on the staffs of the Mississippi State Sanatorium for Tuberculosis in Sanatorium, Pennsylvania State Sanatorium for Tuberculosis in South Mountain, Pa., Essex County Sanatorium for Tubercular Diseases in Verona, N. J., and the Arkansas

Tuberculosis Sanatorium in State Sanatorium; died in the Veterans Administration Hospital May 31, aged 63.

Roth, Charles Rudolph Ⓜ Chicago; Northwestern University Medical School, Chicago, 1906; associated with the Illinois Masonic Hospital; died June 8, aged 82.

Russell, Grover Cleveland Ⓜ Jackson, Miss; Medical Department of Tulane University of Louisiana, New Orleans, 1909; at one time practiced in Johns, serving as health officer of Rankin County for many years; associated with the Mississippi Baptist Hospital; died June 8, aged 74.

Russell, Marion Fore Ⓜ Great Bend, Kan.; born in Alma, Va., Aug. 23, 1884; University of Pennsylvania Department of Medicine, Philadelphia, 1907; past-president of the Barton County Medical Society; fellow of the American College of Surgeons and president of the Kansas Chapter; served as county coroner; for many years associated with the Boy Scout movement and in 1943 was honored with the Silver Beaver Boy Scout award; member of the staff of St. Rose Hospital, where he was chief of staff from 1937 to 1945; past-president of the Great Bend Rotary Club; a director of the American State Bank; vice-president and a director of the Prudential Building & Loan Association; died May 31, aged 74.

Sanford, Benjamin Bentley Ⓜ Portland, Maine; Tufts College Medical School, Boston, 1924; veteran of World War II; served as a colonel in the U. S. Air Force Reserve; died May 25, aged 59.

Stadulis, Ignatius Martin, Wilkes-Barre, Pa.; Jefferson Medical College of Philadelphia, 1924; veteran of World War I; medical inspector for Hanover Township schools for many years; on the staff of the Mercy Hospital; died June 1, aged 60.

Stanley, Thomas Eldridge Ⓜ Richmond, Va.; Medical College of Virginia, Richmond, 1932; interned at the Hospital of St. Vincent de Paul; served as chairman of the school board of Hanover County; a staff member of St. Elizabeth's Hospital, where he died June 3, aged 50.

Stewart, James Leon, New York City; Université de Lyon Faculté de Médecine et de Pharmacie, France, 1919; associated with the French Hospital, where he died April 19, aged 67.

Schnitzler, Friedrich Wilhelm Ⓜ Woodmere, N. Y.; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1921; died May 22, aged 69.

Stone, William Ernest Ⓜ Boonville, Mo.; Washington University School of Medicine, St. Louis, 1918; veteran of World Wars I and II; past-president of the Cooper County Medical Society; past-chief of staff at St. Joseph Hospital; died in the Veterans Administration Hospital, Wadsworth, Kan., May 14, aged 67.

Tinsman, Eugene, Orient, Iowa; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1903; served on the school board for many years; member of the medical examining board for the World War II draft and received a citation signed by President Franklin D. Roosevelt and a selective service medal from Congress; died May 24, aged 85.

Watson, Cassius Hinds Ⓜ Brookfield Center, Conn.; Long Island College Hospital, Brooklyn, 1905; served on the faculty of his alma mater; medical director of the American Telephone and Telegraph Company from 1915 to Oct. 1, 1943, when he retired; past-president of the National Safety Council and the American Association of Industrial Physicians and Surgeons; fellow of the American College of Surgeons; formerly associated with the Bushwick and Eastern District hospitals in Brooklyn; past-president of the Stony Wold Sanatorium in Lake Kushaqua, N. Y.; died in Stamford, June 1, aged 80.

Webster, Hugh Martin Jr., Huntsville, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1950; veteran of World War II; died May 30, aged 32.

Wellman, Graham Ormond, Carthage, Mo.; Hahnemann Medical College and Hospital of Philadelphia, 1913; served in France during World War I; died May 28, aged 76.

Williams, Tom Alfred, London, England; University of Edinburgh Faculty of Medicine, Edinburgh, Scotland, 1896; for many years practiced in Washington, D. C.; past-president of the Washington Psychological Society and the Washington Society of Nervous and Mental Diseases; died in Bournemouth, England, May 27, aged 89.

Yale, Arthur Wells, San Diego, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1899; veteran of World War I; died in Bellflower May 23, aged 83.

Zeller, Raymond Bryant Ⓜ Hazlehurst, Miss.; Jefferson Medical College of Philadelphia, 1927; member of the American Academy of General Practice, American Association for the Advancement of Science, and the American Association of Railway Surgeons; for many years secretary of the Tri-County Medical Society; veteran of World War I; past-vice-president of the Jefferson Medical College Alumni Association; past-president of the staff, Hardy Wilson Memorial Hospital; died June 4, aged 58.

FOREIGN LETTERS

BRAZIL

Intestinal Schistosomiasis.—Many surveys carried out in different areas have demonstrated that schistosomiasis, imported from Africa with Negro slaves and neglected for decades, now affects about 4 million persons in Brazil, mainly in the northern tropical section. Federal and state control programs are now yielding appreciable results. At a meeting of the Rio de Janeiro Medical and Surgical Society Dr. Mario Pinotti, Minister of Health, said that in infected districts of seven states the disease is being combated intensively with several methods of attack; in 8 others, where the problem is less severe, only partial measures are being used; and in the remaining states and territories schistosomiasis has not been reported.

The control measures include the use of such chemical molluscacides as copper sulfate and sodium pentachlorophenate. Three or four times a year snail-infested waters are treated with 1 Gm. of the latter per 100 liters. Sanitary engineers are also building water purification systems in rural communities and constructing bath houses and communal laundries with clean water supplies. Unsanitary lakes and streams are being placarded with warning posters. Another measure adopted to combat the disease is the mass treatment of infected persons, with tartar emetic, emetine, stibophen, lucanthone, and other drugs. Free treatment centers were installed by the Ministry of Health. Twenty-seven communities were freed from the disease in 1958, but they must be protected by a strict control of internal migrations of the population.

Gallstone Ileus.—J. von Sonnleithner, of Sanatório São Lucas in São Paulo, operated on a patient with gallstone ileus in whom a large migrating calculus stopped in the first part of the jejunum. This was the 26th such case reported in Brazil. Last year, Helio Silva (*Bulletin of the Brazilian College of Surgeons*) collected a series of 500 such cases from the world literature. In this series the sex ratio was one man to seven women. Most of the patients were over 50 years of age.

Complications After Pulmonary Resection.—Although adequate preoperative treatment and more precise indications in pulmonary resections have markedly lowered the incidence of postoperative complications, such complications after resections for treatment of tuberculosis are still rather frequent. C. Frazzato Jr. and co-workers of the São Paulo Hospital (*Rev. paulista med.* 54:253, 1959) treated 31 patients with pulmonary tuberculosis who had had adequate medical treatment for at least one year. During the preoperative preparation of the patients treatment with isoniazid and streptomycin was continued. In two of four patients given penicillin and streptomycin by inhalation a remission occurred. The remaining patients were operated on. Para-aminosalicylic acid was not used in the preoperative preparation, although some patients had received this drug in previous ambulatory treatment.

The basic indication for resection was a residual lesion after adequate treatment, with or without positive sputum. All patients had obligatory indications for operation: 13 had a cavity in an upper lobe; 6 a cavity in the middle or a lower lobe; 6 fibrosis, atelectasis, and bronchiectasis; one an extensive unilateral lesion and residual lesion after thoracoplasty; and one a tuberculoma of the base of the right lung. Thirty-two resections (10 pneumectomies, 17 lobectomies, and 5 lobectomies with segmentary resections) were performed in the 31 patients. The cavities of all patients were drained under water, since this is a routine procedure at that hospital, where drainage is considered useful postoperatively. Other postoperative measures included antibiotic treatment, sedation (without morphine), early ambulation, fluids by mouth, and specific antituberculosis treatment.

The authors observed 54 complications (not counting 2 of a general surgical nature): residual sack in 10, suppuration in 9, fistula in 8, empyema in 8, shock in 4, hemothorax and pleural hemorrhage in 3, atelectasis and secretions in 2, reactivation in 2, cardiac insufficiency in 2, subcutaneous emphysema in 2, respiratory insufficiency in 2, and total dehiscence in 2. Such complications occurred in 22 patients, but in 6 the complications were so mild (e. g., small effusion or scanty suppuration) that these patients can be grouped with the remaining 9, thus making a total of 15 patients with results considered excellent. Six patients were cured after complications, two continued to have sputum positive for tubercle bacilli, and eight died. The length of postoperative hospitalization was markedly increased by the complications. Fistulas were the most serious complications. Pneumectomy revealed itself as a major surgical risk, since 6 of the 10 patients on whom it was performed died. Serious complications always followed this type of operation and were usually fatal.

The items in these letters are contributed by regular correspondents in the various foreign countries.

The anesthetist has an important role in meeting the problems of secretion. The endobronchial intubations and the tamponment of the drainage bronchus must be the rule in pulmonary resections. Besides preventing internal drowning they permit a better surgical technique. Adequate chemotherapeutic and antibiotic treatments of tuberculosis in the preoperative and postoperative periods not only diminish the incidence of complications but also permit more boldness in the operative indications. Thus, patients with severe infections, cavitation, and even empyema with bronchial fistula can be operated on with success.

Blastomycosis.—J. Machado Jr. and J. L. Miranda (*O Hospital,* May, 1959), reported an epidemiologic study of South American blastomycosis. Between November, 1949, and January, 1959, they studied a series of 238 patients. Those most severely affected were in the 40-to-49-year-old group. There was no indication of frequency related to race. Women were less affected than men, but this was probably due to occupational factors. The infection was most common in farmers. The portals of entry of the parasite were the skin and the mucosa of the respiratory and digestive tracts, especially the oral muscosa.

Paranasal Tumors.—J. F. Barbosa, chief surgeon of the head and neck department of Central Institute of Cancer in São Paulo, analyzed a series of 141 patients with malignant tumors of the paranasal cavities. Of these 116 were Caucasian, 21 Negro, and 4 Oriental; 97 were men and 44 were women. Most of the patients were between the ages of 40 and 70 years. The author treated such patients by removing the upper portion of the ascending branch of the mandible, the lower portion of the temporal muscle, the upper portion of the masseter, the zygomatic arch, and all of the external pterygoid muscle. He exposed, tied, and severed the internal maxillary artery before removing the tumor. All the contents of the orbital cavity and the ethmoid sinus were included in the resected mass. As a rule, he covered the operative cavity with a free flap. The results of this treatment were encouraging.

Pancreatic Cysts.—Although pancreatic cysts are rare, four cases were presented by J. R. Alves, professor at the University of Minas Gerais, in Belo Horizonte. Two were true cysts and two were pseudocysts. In all the patients the diagnosis of pancreatic cyst was made preoperatively. In one there was a concomitant disease of the extrahepatic bile passages. In one there was a simultaneous occurrence of diabetes and trypanosomiasis. One case was probably due to a chronic pancreatitis with pancreatic fibrosis. There is no standardized operation for all cases. Splenectomy was necessary in two cases, owing to the extensive adhesions between the cyst and the spleen. All the patients recovered and returned to their normal activities.

DENMARK

Peptic Ulcers due to Corticosteroids.—A series of 10 patients who had peptic ulcers that developed during long-term steroid therapy with relatively small doses was reported by Aagaard and co-workers (*Acta chir. scandinav.* 116:423-428, 1958-1959). The ulcer involved the stomach in seven, the pylorus in two, and the jejunum in one. All 10 patients were operated on and had no postoperative complications. These ulcers were similar to ordinary gastric ulcers, apart from a less dramatic course during perforation. The steroids have two effects that might be assumed to be important in the development of peptic ulcers; they increase the production of hydrochloric acid and pepsin, and they inhibit fibroblast proliferation during wound healing and delay the formation of granulation tissue.

Types of Honors.—When one has reached the age of 70, or thereabouts, and has had a distinguished career, one's admirers may wish to express their appreciation by a collection containing original articles—many perhaps of great value. When such a volume is published by itself and not as a part of, or supplement to, a well-established medical journal, it often escapes the notice of librarians and others engaged in indexing and cataloging medical literature. The smallness of the mailing lists of some collections of this sort may contribute to the burial of their contents. To escape this fate B. Ibsen (*Nordisk medicin,* April 23, 1959) presented some alternatives. If the collection is to survive as such, it must be published in a medical journal with a substantial mailing list. If such a literary testimonial is not contemplated, the prospective contributors might find a channel for their emotions in the establishment of a prize to be given in the name of their idol. The award, from time to time, of this prize to some worthy recipient would remind the world of its debt. On the other hand, a fund collected in honor of the distinguished scientist might be earmarked for the remuneration of lecturers on given subjects. The author's pet idea, however, was to send the beloved septuagenarian on a journey to enlighten others by giving lectures himself.

Rehabilitation of the Nervous Patient.—K. H. Backer has published, through the University of Copenhagen, a monograph in which he reviews, from the point of view of rehabilitation, the fate of the patients discharged from the surgical and medical wards of a large Danish hospital in 1949. The rehabilitation movement at first stressed such dramatic ailments as paralysis, spasticity, blindness, deafness, and crippling. These tended to overshadow the less striking mental handicaps, which, in the form of mild neurosis, psychopathy, or just slight mental deficiency, have interfered with wage-earning and a congenial mode of life. The author makes an urgent plea on behalf of the latter group.

Two 50-Year Jubilees.—In 1909 the National Health Service (NHS) and the Medical Jurisprudence Council came into being. Both have earned the general esteem they now enjoy by the skill with which their leaders have made them indispensable to the community. The present head of the former body, J. Frandsen (*Ugeskrift for laeger*, April 23, 1959), states that his predecessors had to fight in order to fit adequately into the machinery of a modern welfare state. With responsibilities to such important activities as dentistry, nursing, and pharmacy, to mention only three of the many spheres in which the NHS is interested, it acts in rather an advisory than a disciplinary capacity, not being a ministry of health nor the health department of some ministry or other. It is an autonomous institution, beyond the bounds of a central administration although connected with it and with local administrations. So long as the health activities of the country are decentralized, the NHS can successfully meet the calls made on it.

In *Ugeskrift for laeger* for April 30, Prof. K. Sand, head of the Medical Jurisprudence Council for over 30 years, traced its history since its birth in 1909. Here, too, is a record of prodigious growth from modest beginnings. With the growth of a third powerful organization, the Danish Medical Association, which works in close cooperation with the NHS, Denmark has built up a system of public health which may well serve as a model for other countries.

Pertussis Vaccination.—At the state serum institute in Copenhagen tests have been made for some time with a triple vaccine against diphtheria, tetanus, and pertussis, with a view to observing the severity and frequency of its side-effects. While awaiting a final verdict attention is being focused on pertussis vaccine alone, as given to prevent whooping cough early in infancy. As pointed out by H. Lautrop and co-workers (*Ugeskrift for laeger*, May 21, 1959) whooping cough continues to take a heavy toll of life in Denmark, with an average of about 25 deaths a year. About 75% of these occur in children under 1 year of age. There is also an unknown number of cases of bronchiectasis and other sequels to whooping cough that are not immediately fatal, hence the advice to start vaccination against it as early as the 5th week of life. Two further injections should then be given at intervals of a month, to be followed about a year later by a fourth injection. In the absence of such prophylactic vaccination it may be permissible to fall back on therapeutic injections just before or at the outbreak of whooping cough, but no extravagant claims can be made for such action.

Addiction to Tranquilizers.—J. Schou (*Ugeskrift for laeger*, April 23, 1959) stated that in 1958 over 24 million grams (61 million 400-mg. tablets) of meprobamate was sold. It is so popular with would-be suicides that 33 cases have already been reported in which it was the sole agent, in amounts varying from 8 to 40 Gm., in an attempt to commit suicide. None of these attempts proved fatal. In another series of attempted suicides in which meprobamate was given with a barbiturate there were two deaths. Although there were no deaths in the first series, the author warned against a too light-hearted prognosis, as only 6 Gm. given by mouth may induce a dangerous comatose intoxication. The risk of meprobamate addiction is now regarded as being so serious in Denmark that the author warned against its use for the cure of tobacco addiction.

Thallium Poisoning.—A discussion at a recent meeting of the Danish Society for Internal Medicine (*Nordisk medicin*, May 21, 1959) showed how polymorphous the manifestations of poisoning with thallium may be, whether it is taken in an attempt to commit suicide or by accident. In one series of six cases there were five in which thallium destined for rats and mice had been taken by mistake. Alopecia has been said to be a sure sequel to thallium poisoning, but it was observed in only two of these cases. The diagnosis of thallium poisoning may be comparatively easy when the characteristic alopecia appears several days after the poison has been taken, but it is less so when the clinical findings are suggestive of poliomyelitis. One of the patients in the above-mentioned series underwent a laparotomy, since violent colic had seemed to indicate thrombosis of some mesenteric vessel. One speaker at this meeting stressed the diagnostic value of tests of the urine for thallium, which in one of his patients was found in such quantities as to indicate that a lethal dose had been taken. As a result of prompt action the patient recovered, however.

FINLAND

Postoperative Biliary Stones.—Operations for biliary stones are sometimes complicated by concrements retained in the biliary ducts. A conservative method for the removal of such concrements is based on the lipid-dissolving property of ethyl ether. The chief reasons for the retention of stones in the biliary ducts are that they are situated high in the hepatic ducts, whence they may later migrate with the bile flow down into the common bile duct; or that by the action of inflammatory processes the stones may become imbedded in the wall of the common bile duct or hidden in a cystlike cavity near the duodenal papilla, thus escaping observation; or, finally, that obesity or impaired general condition may limit the surgical possibilities and render operative cholangiography difficult. Alfthan and Köhler (*Acta chir. scandinav.* 116:437-449, 1958-1959) reported on 24 patients aged 27 to 68 years, in whom postoperative residual biliary tree stones were found. These patients represented 1.4% of all who had had operations for gallstones performed in the period 1954-1958. Of the 24 patients 14 were relieved of stones. From a clinical point of view ethyl ether seemed to be the best of all lipid solvents. Chemical analysis or, at any rate, a dissolving test in vitro before treatment, was recommended.

In the beginning the treatment should be cautious. Either the initial doses of ether should be small (about 0.5 ml.) or the ether should be given through a double-barreled tube, allowing the vapor to escape when the pressure rises. The authors did not observe any harmful side-effects of the ether. Concrements larger than 1 cm. in diameter can seldom be dissolved, and therefore comparatively early reoperation for such stones is indicated. Intrahepatic stones dissolve slowly and demand persistence. Small, common-duct stones generally dissolve within two to three weeks. A single dose of ether remains in the biliary ducts for about 10 minutes. The authors therefore recommended frequent treatments, prolonging the action of the ether as much as possible each time. Operative cholangiographies of a high technical standard probably afford the best possibility of visualizing stones in the biliary tree and should be made, if possible. If, however, stones persist in the biliary ducts, the authors recommend ether treatment first. Only if this procedure failed should reoperation be performed.

INDIA

Induced Cardiac Arrest.—A. K. Basu and co-workers (*Indian Journal of Surgery*, vol. 21, April 1, 1959) induced cardiac arrest in adult monkeys by using two salts of potassium citrate: potassium chloride and acetylcholine. The experiments were done in both hypothermic and normothermic animals, after anesthesia was induced with an intravenous dose of thiopental and intratracheal intubation. Cooling was done by immersion and by rubbing ice on the hide, the range of hypothermia varying from 29 to 30 C (84 to 86 F). Cardiac arrest with acetylcholine occurred within a few seconds of administration of the drug. The myocardium retained a certain amount of tone and was not completely flaccid during the arrest. The revival of cardiac rhythm and contraction was easier and more spontaneous than when potassium salts were used. The incidence of fibrillation was less with acetylcholine, and, even if it did occur, it could be easily controlled. An injection of atropine served as an effective antidote, causing a smooth and quick reversion.

The disadvantage of acetylcholine was that the arrest it produced was temporary and often incomplete. This was seen in both hypothermic and normothermic animals. Even as large a dose as 300 mg. did not produce total arrest. The recovery in normothermic animals was even smoother than in hypothermic animals. Fibrillation did not occur in any of these animals. Thus, hypothermia did not offer any added advantage but on the contrary caused minor periods of fibrillation in the recovery phase. The dose of potassium salts varied from 75 to 300 mg., depending on the weight of the animal. The asystole induced by these salts was completely flaccid and absolute, the duration varying from 5 to 19 minutes. Some animals, however, had a definite but variable latent period between the injection and the arrest. Cardiac dilatation and ventricular fibrillation occurred in almost all animals during recovery. The duration and severity of these fibrillatory episodes was much more marked than after acetylcholine, and there was no certain way of terminating them as there was when acetylcholine was used.

Potassium-induced arrest was considered to be of greater help in open cardiac surgery than that induced by acetylcholine, because of the complete flaccidity of the myocardium and the longer duration of the asystole. Its disadvantages were the constant occurrence of cardiac dilatation on releasing inflow occlusion and the development of severe ventricular fibrillation before the return to sinus rhythm. Manual cardiac massage was found useful for treating fibrillation, but it had to be continued for a long time (19 minutes in some animals) before normal rhythm was reestablished. Calcium chloride injection was of doubtful value in treating fibrillation, and coronary infusion of sodium lactate solution was of no value. Hypothermia was of great help in potassium-induced arrest. Of the 11 animals on whom hypothermia was used 8 survived, while survival was rare in the normothermic controls. No brain damage could be detected in the hypothermic animals in whom fibrillation lasted for more than 15 minutes and in whom normal rhythm was ultimately reestablished by massage.

In the same issue P. K. Sen and co-workers reported a study on healthy mongrel dogs in which they assessed the action of different cardioplegic agents, alone and in combination. Anesthesia was induced with intravenous administration of thiopental sodium, and positive-pressure ventilation with air by a respiratory pump through an endotracheal tube was used from the start. Inflow occlusion was practiced on all animals before bringing about chemical cardiac arrest. The cardioplegic drug was injected into the ascending part of the aorta till the heart stopped in diastole. After allowing a certain interval, depending on the type of arrest, various substances were used to wash out the cardioplegic drug, such as whole blood, Ringer's solution, 5% dextrose solution, normal saline solution, and 10% sodium lactate solution. In many animals injections of calcium and epinephrine and cardiac massage had to be resorted to for restitution of heartbeats to normal rhythm. Hypothermia was produced by immersion in an ice-cold water bath when required, the hypothermia being only of moderate depth (about 28 C [82.4 F]).

The various chemical agents tested were potassium citrate alone, acetylcholine alone, combination of potassium citrate and acetylcholine, potassium citrate and acetylcholine under hypothermia, potassium chloride and acetylcholine under hypothermia, and a combination of magnesium sulfate, potassium citrate, and prostigmine. Nine dogs received potassium citrate alone, a 25% solution being used for the first dog, a 10% solution for the next, and a 5% solution for the rest, its amount varying from 250 to 1,250 mg. All the hearts went into ventricular fibrillation during recovery after a diastolic arrest of one to four minutes. Manual cardiac compression and injections of calcium chloride, epinephrine, and occasionally neostigmine were necessary for restitution. Another group of nine dogs received acetylcholine alone. Diastolic arrest occurred within a few seconds but lasted less than a minute. Normal rhythm was restored in all but one who developed ventricular fibrillation. There was no evidence of brain damage in the dogs that survived, the longest survival time being eight days.

Five dogs were injected with acetylcholine and potassium citrate, the former in the same dose as in the second group and the latter in 1% solution in amounts varying from 60 to 100 mg. Diastolic arrest occurred rapidly in all and restitution was started after an interval of two to five minutes. Four animals came back to normal with massage alone, and one required an injection of calcium chloride. Ventricular fibrillation developed in all animals during this process, and it remained permanent in one. The time required for restitution ranged between 4 and 20 minutes and all showed evidence of brain damage. Thirteen animals received the same combination as had the previous group under hypothermia ranging between 30 and 32 C. Diastolic arrest was immediate and was maintained for two to seven minutes. Three animals required intracoronary calcium chloride injection besides massage for restitution, the time required for restitution varying between ½ minute and 20 minutes. Brain damage was definite in two and possible in two others. There were no long-term survivals.

Ten dogs received a combination of 1.2% potassium chloride solution and 2% acetylcholine solution under hypothermia of 30 C. Diastolic arrest was obtained in all within one to four minutes. Six dogs were revived with cardiac massage of one to seven minutes' duration and the remaining four did not respond to either massage or an injection of calcium chloride. Seven developed ventricular fibrillation during restitution. Ten animals were treated with a mixture of magnesium sulfate, potassium citrate, and prostigmine, after induction of hypothermia of 30 C. Diastolic arrest was maintained for two to four minutes in all, but the arrest occurred after a latent period of one-half to two minutes after injection. Seven animals were restored to normal by massage, and some also required an injection of calcium chloride. The time necessary for restitution varied between 2 and 23 minutes. Ventricular fibrillation occurred in only three dogs, one of which was restored to normal after 23 minutes of cardiac massage and an intracoronary injection of calcium chloride. The other two could not be revived.

Thus, of all the agents used, acetylcholine had the most rapid action but the arrest was incomplete and of short duration. Potassium-induced arrest was rapid and complete but recovery was uncertain, often late, and accompanied by ventricular fibrillation. A combination of these two exhibited the balanced action of rapid diastolic arrest of relatively shorter duration but an easier restitution of rhythm. The incidence of ventricular fibrillation was, however, as frequent as with potassium alone. A mixture of magnesium sulfate, potassium citrate, and prostigmine produced a slower but definitive diastolic arrest with the least incidence of ventricular fibrillation and a reversible cardiac standstill.

JAPAN

Artificial Insemination.—According to the *Tokyo Weekly* (May 31, 1959) the Department of Family Planning of Keio University School of Medicine celebrated the 10th anniversary of its successful artificial insemination program. The first child resulting from artificial insemination in Japan, a girl, is in the fifth grade and is bright and pretty. In the past 10 years 300 babies were conceived by this method. Understandably the mothers prefer to remain anonymous. Because of this the director of the department is handicapped in carrying out a complete follow-up study. More than 50% of the mothers ignore questionnaires. After becoming pregnant many mothers prefer to be delivered elsewhere and are lost to the study. In many cases two or three inseminations are required before pregnancy occurs. If after 6 attempts conception does not take place the would-be mothers receive no further encouragement.

The candidates are first referred to the gynecologic department for a potency test, biopsy of the endometrium, and culture of menstrual discharge for tubercle bacilli. If these tests reveal no abnormality, a sample of the husband's semen is examined. If this is found to be deficient in any way both parties are asked to sign a document, separately, giving unqualified consent to the use of the stock sperms. Ovulation is presumed to coincide with the elevation in body temperature of the prospective mother, who is instructed to visit the clinic on the day of presumed ovulation. Reasons given for requesting artificial insemination included the fact that (1) the husband worked in an atomic energy plant and the couple feared damage to his sperms, (2) husband and wife were related and they feared passing on a hereditary disease, and (3) husband and wife were separated but the wife still desired a child of her own. The sperm stocks used were procured from medical students or athletes who received a small fee. Controversies arising from various aspects of this subject have not yet been resolved.

UNITED KINGDOM

Ultrasonic Vibrations.—Because of the danger of exposing the fetus to x-rays, tests are being carried out in the department of obstetrics of Glasgow University to ascertain if the fetal and maternal abnormalities that are detected radiologically at present may be determined by ultrasonic vibrations instead. In most hospitals the number of radiologic examinations during pregnancy is being reduced to a minimum because of the hazards of irradiation to the fetus. Two physicists have been appointed to the Western Regional Hospital Board in Scotland and funds allocated to study the diagnostic uses of ultrasonic vibrations such as have already been used for the diagnosis of abdominal tumors.

Culture of Sarcoid Tissue.—Lundbek and co-workers reported the successful culture of sarcoid tissue from lymph nodes and skin by means of the plasma-clot technique (*Brit. J. Exper. Path.* 40:61, 1959). Lymph nodes from the supraclavicular fossae or skin sarcoids were removed under local anesthesia and cultured in plasma-clot or bovine amniotic fluid enriched with horse serum and bovine or human embryonic extract. Within a few days the tissue fragments were surrounded by a carpet of fibroblasts, which became swollen and enlarged, their chromatin became coarse, and the cells gradually rounded off. These changes were patchy. In nearly all of these patches a number of giant cells developed. Most of the cells contained large eosinophilic cytoplasmic inclusions. These changes were not seen in lymph nodes and skin removed from patients with other conditions associated with lymphadenopathy, such as Hodgkin's disease. The cytoplasmic inclusions could have resulted from the activity of an infectious agent, although this was not proved. Tests are being made to see if these inclusions can be maintained by passage. Attempts to establish transferable cytopathogenic effects with sarcoid lymph nodes and skin in human embryonic lung tissue cultures failed.

Cost of Drugs.—According to the final report of the Hinchliffe Committee the drug bill in relation to the total cost of the National Health Service (NHS) in England and Wales has doubled in the last nine years, despite efforts to curb it. Making allowance for the fall in the value of money, this represents a real increase of about 45% since the fiscal year 1949-1950. While there is no evidence of widespread and irresponsible extravagance in general practitioners' prescribing, there is room for economy. The tendency to order larger quantities of each prescription than are required involved some waste. The cost of the average prescription has risen from 43 to 84 cents, and the average cost of drugs per patient a year has risen from $2.27 to $4.20. No explanation was found for the continuing per capita rise in prescriptions in a period when the improved efficacy of drugs should have shortened the length of illness and returned people to health and work sooner.

The committee recommended that physicians be given more information on prescribing, especially about the costs and advantages and disadvantages of new drugs. They should not prescribe expensive preparations when simpler, equally effective, preparations are available. There should be no ban on the prescribing of new drugs but, until the results of clinical trials are known, doctors should prescribe new drugs only when existing ones have failed. If a given doctor's costs habitually exceed the local average by more than 50% the reason should be sought by the local medical committee. The penalties for excessive prescribing, particularly if a physician prescribes extravagantly to attract patients, should be severe. Some patients exert pressure on their doctors to prescribe particular drugs for them. Posters and notices should be supplied for offices warning patients against "getting the medicine habit."

All medical schools should be encouraged to take an interest in economy in prescribing. More students should spend short periods with general practitioners. There is an urgent need for systematic postgraduate instruction of general practitioners in pharmacology and therapeutics. Every consultant should exercise a proper economy in his own prescribing for hospital patients. Everything possible should be done to prevent public money from being wasted in inflated and expensive sales promotion. The drug industry should be asked to curb the more extreme forms of advertising. New drugs should be subjected to independent controlled clinical trials as early as possible with speedy publication of the results. One of the committee's chief recommendations was that an advisory body including men with business experience, an economist, and a statistician, be appointed to advise the Minister of Health at an early date on matters affecting drug costs.

Referring to new drugs, the committee said that 18% of all NHS prescriptions in 1950 were for proprietary drugs. This proportion rose in 1957 to just under 50%. In the same period the value of proprietary drugs rose from about 40 to over 67% of the total cost of prescriptions, measured by the cost of ingredients. A recent estimate showed that two groups of drugs, antibiotics and hormones, were together responsible for almost 35% of the total ingredient cost of proprietary preparations.

Doctors Urged to Unite.—British Medical Association leaders urged the 40,000 National Health Service doctors to unite in readiness for a dispute with the government over the report of the Royal Commission on Doctors' and Dentists' Remuneration and any action necessary to back their pay claim. The policy of the 21,000 family physicians was laid down at the annual conference of representatives of local medical committees in London in June. The General Medical Service Committee, which negotiates for family doctors, said: "Under extreme provocation the profession should reserve the right to withdraw from the service." The committee will recommend a total withdrawal of service, with a return to private practice, in the event of an unresolved dispute with the government, but, it warns, that such action would be possible only if the profession was united and resolved to make a stand on principles rather than on matters of remuneration alone.

Hypertension.—A. W. D. Leishman of the United Sheffield Hospital (*British Medical Journal*, May 30, 1959) has followed the progress of 211 untreated hypertensive patients regularly since 1946 and compared it with that of 73 patients treated by lumbodorsal sympathectomy and 118 treated with ganglion-blocking drugs. Half of the untreated patients are dead, and a study of these cases has confirmed that high diastolic pressure, male sex, and the presence of albuminuria or retinopathy are particularly unfavorable features. Changes evident in the electrocardiogram did not appear to influence the prognosis. Rise of blood pressure in untreated patients was uncommon, but in 20 of 176 patients the diastolic pressure increased by 20 mm. Hg. Seven of these developed malignant or accelerated hypertension. This could not have been foreseen when they were first examined. A satisfactory fall in blood pressure was achieved in 80% of the patients who underwent lumbodorsal sympathectomy. The unusual permanence of these results was attributed to extensive dorsal denervation. Ganglion-blocking drugs were given parenterally. Of the patients at present on treatment, 67% were regarded as well controlled.

The treated and untreated groups were judged to have been of equal severity, and comparison of their respective mortality rates was made. Except in malignant hypertension the death rate among treated patients was in no instance appreciably higher than one-third that of the untreated group. Although the length of observation of drug-treated patients was not yet adequate for strict comparison, these figures left no doubt that lives had been extended by both forms of hypotensive treatment. Reduction in the number of fatal strokes was a notable feature. Judged from the fate of untreated patients, the use of ganglion-blocking drugs seemed justified in any person whose diastolic pressure was consistently above 120 mm. Hg, and in the presence of albuminuria it might be advisable when blood pressure was below this level. Hypertensive women, however, did not normally require this treatment unless the diastolic pressure was at least 130 mm. Hg.

M. J. D. Newman and J. I. S. Robertson of St. Mary's Hospital, London, reported in the same issue that they made a survey of 104 patients with initial diastolic pressures over 120 mm. Hg. Most of these patients were treated with ganglion-blocking drugs. The complications occurring were related to the degree of control of the diastolic pressure. In patients with retinal hemorrhages and exudates or papilledema the prognosis was closely related to the degree of lowering of the blood pressure. In those patients with cerebral or cardiac vascular lesions no such relationship could be clearly discerned. Uncomplicated hypertension has a comparatively good prognosis without treatment, and a much larger series would be required to demonstrate any effect of hypotensive drugs.

Cancer Research.—In the British House of Commons, Mr. Sydney Irving asked how much money would be spent by the Minister of Health on cancer research this year. The minister replied that expenditure from public funds on cancer research was mainly undertaken by the Medical Research Council, which expected to spend $1,624,000 for this purpose during the current year, including a grant of $578,000 to the Institute of Cancer Research. Cancer research is also carried out in the National Health Service in the course of treating patients, but it was impossible to make a separate estimate for the expenditure involved. Mr. Irving had nothing but praise for the effort made by voluntary agencies, but he found it hard to understand why, in the attack on this terrible disease, so much of the burden should fall on voluntary effort.

Redundant Consultants.—An annotation in the *British Medical Journal* of June 6 said, with reference to the reinstatement of a dismissed consultant, that the way is now open for belated justice to be accorded to Mr. A. H. Barber, the Oldham gynecologist whom the Manchester Regional Hospital Board wrongfully dismissed in 1952. The Minister of Health has amended the National Health Service Regulations so that now regional boards may offer employment to redundant consultants without creating competition. The new regulations became effective May 27 and apply to Scotland, England, and Wales. After a seven-year battle, which included a successful high court action, repeated pressure on the Ministry by the British Medical Association (BMA) and the Joint Consultants Committee, a campaign in the lay press, and questions in both Houses of Parliament, bureaucratic rigidity and inertia are exposed. It now remains for the Manchester board swiftly to find suitable work for Mr. Barber.

The new regulations go much further than making justice for one man administratively possible. Clause 16 of the Terms and Conditions of Service of Hospital Medical Staff is the only safeguard for consultants against unfair dismissal. It is written into their contracts with regional boards. For a long time the BMA and the Joint Consultants Committee have been imploring successive ministers of health to give substance to their paternal assurances and certainty to their understanding of moral obligation. The new regulations appear to do this. "When as a result of contraction of work or of local reorganization," states the Ministry's explanatory memorandum to hospital authorities, "it becomes, or has become, necessary for a board to terminate the appointment of a consultant or a senior hospital medical or dental officer, the board should first consider whether they can vary his contract and offer him alternative employment. An appointment offered in these circumstances need not necessarily be in the same specialty as the officer's existing post, provided that he has the necessary qualifications for the new post." If the board has no post to offer, and the officer assents, the board should notify all other boards. This is a step toward remedying a serious defect in the terms of employment in the hospital service.

Mammary Cancer.—For many years radical mastectomy, either alone or in combination with radiation therapy, was generally considered the best treatment for operable cases of breast cancer. This, however, has been challenged by McWhirter, of Edinburgh, who advocated simple mastectomy, followed by postoperative irradiation of the axilla, supraclavicular glands, and chest wall for all but advanced cases. Watson has compared the gross five-year survival rates of patients treated by the two methods (*Lancet* 1:1191, 1959). McWhirter's five-year survival rate for 1,882 patients at Edinburgh Royal Infirmary, treated when feasible by simple mastectomy and postoperative irradiation, was 42%. Watson's figures were obtained from the Saskatchewan Cancer Treatment Service, which operates under the auspices of the Canadian government. In the Saskatchewan series 1,055 patients were treated by radical mastectomy and in most this was followed by irradiation. The gross five-year survival rate was 52%. The difference is statistically significant in favor of treatment by radical mastectomy and irradiation.

Athlete's Foot in Children.—The incidence of athlete's foot in school children was studied by English and Gibson (*Brit. M. J.* 1:1442, 1959). Nearly 4,000 boys and girls aged 11 to 14 and 894 boys aged 7 to 10 were examined clinically and mycologically for dermatophytosis. Of the older boys 40% had lesions of the feet and from 6.6% fungi were isolated. The corresponding figures for the younger boys were 33 and 2.2%, and for the girls 30 and 1.6%. The incidence of dermatophytosis increased gradually to the age of 11 and then fluctuated irregularly. Among the children from whom the organisms were isolated 1.5% were symptomless carriers. No correlation was found between infection rate and personal cleanliness, social class, or the use of school showers. By far the most common infecting fungus was Trichophyton mentagrophytes, which caused 84% of the infections. Trichophyton rubrum was responsible for 7.2% and Epidermophyton floccosum for 4%.

There was a close correlation between infection and proximity of the schools attended by the children to swimming pools. It was concluded that the local swimming pool is an important focus of fungal infection. T. mentagrophytes was, in fact, repeatedly isolated from the floors of these pools. The fungus was found more often in pools used by children with a high incidence of dermatophytosis than in those used by children with a lower incidence. Spread in swimming pools was thought to be by infected fragments of skin pressed on the foot while walking over contaminated floors. Members of the swimming pool staff whose duties entailed their entering the water were also found to be infected. Almost continuous cleaning and sluicing would appear to be the only practical ways of preventing infection from these pools.

Infective Hazards of Water Closets.—Experiments made by Darlow and Bale have shown that flushing a wash-down type of water closet can produce a bacterial aerosol of sufficient magnitude to be an infective hazard (*Lancet* 1:1196, 1959). Any process involving splashing or frothing produces droplets, which remain suspended in the air for a variable period, depending on the mass and evaporation rate of the droplets, and the velocity and direction of local air currents. If the liquid contains solid matter in solution or suspension, an aerosol of droplet nuclei will persist after the evaporation of the rest of the droplet, and may be infective. It is not unreasonable to expect that some fecal pathogens can produce infection by inhalation. Furthermore, excreta may contain causative organisms of diseases that affect systems other than the gastrointestinal tract, such as Mycobacterium tuberculosis, poliovirus, and the Coxsackie and ECHO viruses. The authors demonstrated that the flushing of a water closet generates sizes of particles capable of penetrating to the lower respiratory tract as well as of deposition in the nose, mouth, eyes, and on surfaces touched by the hands.

Experiments were carried out with Serratia marcescens as a test organism for the inoculation of an experimental water closet. A sampling apparatus was mounted at varying levels above it. The maximum number of colonies found on the test plates after flushing was 4,000, representing a mean of 2,000 particles and 19,000 organisms per cubic foot of air. The persistence and wide dissemination suggested that many of the particles were small and tended to remain airborne. It was calculated that about 4,500 particles escaped into the room at each flushing. Aerosol formation was not prevented by the use of the weak disinfectants normally employed in the home.

Family Doctor Center.—On June 1 the Family Doctor Center, at Livingstone House, Edinburgh, was opened. Its object is to provide diagnostic facilities for general practitioners in the area, so that they can deal with some patients whom they would otherwise have to send to the local hospitals for diagnosis and, perhaps, treatment. They will be able to bring any patient to the center whom they would like to investigate more fully than their office hours and facilities would normally permit. The center provides a full range of diagnostic facilities. Its use will be restricted to 40 doctors to avoid overtaxing its resources. This number was selected by ballot from over 100 physicians who applied to use the center. If the center is a success others may be built to increase the facilities of doctors in the National Health Service (NHS). The staff consists of an administrative secretary, stenographer, nurse, laboratory technician, medical social worker, radiographer, part-time radiologist, and part-time medical adviser. The center has fully equipped examination rooms, a clinical laboratory, an x-ray room, and an electrocardiograph.

This center should help to remedy one of the defects in the NHS. Many doctors are frustrated because they cannot get tests done on patients without putting them through the diagnostic routine of the big hospital. Often a physician requires only a simple x-ray or a follow-up blood test on a patient, which he cannot get from the hospital except in an emergency, without a long wait. Confirmation of a general practitioner's diagnosis is often delayed for weeks because the patient is referred to a hospital outpatient service, where diagnostic tests may be done at the rate of one a week.

The new center will give the required diagnostic information within a few hours and will provide facilities for the chronically ill, particularly the patient who is mentally ill, or has a multiplicity of symptoms and visits the doctor frequently. Then the medical social workers will be able to help. It is also hoped that the center will bring family doctors together to discuss their diagnostic problems. It is housed in the premises of the general practice teaching unit of Edinburgh University and should thus provide a link between the medical students and general practitioners there.

Temperature of the Brain During Hypothermia.—The safe duration of circulatory arrest in cardiac surgery under hypothermia is limited by the viability of the central nervous system, particularly the vital centers in the brain, the lower the temperature the longer being the time available. The temperature of the brain at the moment that blood flow to it is stopped is the all-important factor in determining the safe period of circulatory arrest. Hitherto, it has been assumed that the temperature of the brain substance is close to that of the nasopharynx or lower third of the esophagus, but this has never been demonstrated.

Hercus and co-workers (*Brit. M. J.* 1:1435, 1959), using an electric thermometer, took simultaneous temperature readings of the rectum, lower third of the esophagus, nasopharynx, right atrium, and cerebral cortex in sheep. A small drill hole was made in the skull to reach the brain, and the right atrium was reached by passing a cardiac catheter through the jugular vein. The body temperature was lowered to 29 or 30 C by immersion in iced water kept at 1 to 2 C. Over the range 29 to 32 C the temperature recorded in the lower third of the esophagus approximated closely to that of the brain. Rectal and nasopharyngeal temperatures did not show such close agreement, as they reflected changes in blood and brain temperatures sluggishly. Under the condition of the test the rectum required 15 to 20 minutes to reach a stable temperature, whereas the central blood, esophagus, and brain temperature became stabilized in five minutes. The aortic blood temperature was always within 0.2 C of the temperature in the lower esophagus. This close correlation between the temperature in the lower third of the esophagus and the cerebral cortex makes it the logical site from which to record the body temperature during operations under hypothermia.

CORRESPONDENCE

THE HOSPITAL SHIP CONSOLATION

To the Editor:—As one who has spent much time in the Far East teaching and helping set up psychiatric work in China, the Philippines, Indonesia, and Thailand (I am returning to Bangkok in November for another four months of teaching at the medical schools there) and as one who has spent the last 38 years teaching psychiatry at Harvard, New York University, and the University of California, where I have taught many doctors from the Far East, I have been much interested in the announcement of the project to spend $3,500,000 to put the hospital ship Consolation into shape and to send a group of physicians, nurses, and public health workers to the Far East, mainly Indonesia.

I would like to register my own feelings about spending $3,500,000 to send this hospital ship to Indonesia. Just lately I heard that two additional ships may be taken out of mothballs next year and sent to the Far East. It is difficult for me to see what lasting good will be accomplished by a project of this sort, whereas it is obvious that the spending of this amount of money to carry out long-term steady work in these places in the Far East would yield many times the good results of sending a hospital ship. It seems possible to me that sending a ship like this may even have the opposite effect from that desired. It is a sort of spectacular grandstand play showing the great wealth and medical facilities of the United States, but how much good actually will be done in the treatment of sick people and how much can thus be done in the way of medical and nursing education in countries such as Indonesia?

For $3,500,000 one could build an excellent medical school with hospital facilities and staff it with teachers for several years—surely something that would have much more lasting value than the hospital ship. I must confess my feeling that this sort of gesture is something that will give emotional satisfaction to some Americans, including many of those participating in the project, rather than do lasting good in Indonesia.

Probably now it is impossible to reconsider and study whether this same amount of money can be used to better advantage in some other project. I do find it difficult to understand why a scheme of this sort should have been rushed into without getting the opinions of some of the doctors who have training and experience in medical work in the Far East and are most qualified to help evaluate what would be the best way to spend such a large sum of money.

Even if it is too late to stop or change this project, it is not too late to plan for a good evaluation of it and to consider carefully the worth of any continuation of this project or the launching of similar ones. Although it seems to me that it would be difficult to estimate the final results of a project of this sort because the native countries and groups involved will be extremely polite and will not openly express any criticisms which they may have, I do believe it is most important that such an evaluation be attempted and that no further projects be activated without an evaluation and a comparison of the use of a hospital ship with other ways the money might be spent.

San Francisco 14.

To the Editor:—I am delighted to read of the interest and support which the American Medical Association is giving to the "People to People" program between the United States and other countries, but I cannot refrain from voicing some apprehension with regard to the form which this support is taking. I refer to the use of the hospital ship Consolation as a sort of floating medical center and hospital visiting "Southeast Asia." To outfit and run the ship for one year will require $3,500,000.

This amount of money would go far in equipping a permanent medical school, in underwriting visiting teams going over to stay at the medical schools, and in giving advanced training to potential faculty from the foreign country. While perhaps not as dramatic and spectacular, I believe the latter style of educational program would have more lasting effect and in many ways be more acceptable as well as practical.

Except for the health services of the smaller islands (and these needs are now met by our Navy, the British, and the French, as the responsibility lies), a visit by a hospital ship is hardly the best approach for an educational program. From our experience, short, quick visits from American faculty are of little permanent value. I fear it would be little more than a traveling clinic. It could alleviate many of the immediate and acute illnesses but this is a drop in the bucket compared to the over-all health problem presented by the more populous countries of Southeast Asia. Those problems will best be solved by well-trained native health professionals and by long-term investment in education in medicine and public health. At best, the educational programs under Point IV are too much of an impact phenomenon and do not recognize the need for a slower or sounder approach and maturation.

I believe that the psychological effect of a hospital ship will, on the one hand, tend to separate our visiting group from the host nationals and, on the other, may prove somewhat confining for the morale of the long-term American staff. The matter of language and customs poses many problems in dealing with the sick, whether ambulatory or hospitalized. I am sure it will require much aid from our foreign service personnel. It is conceivable that in some areas it will not be welcome. If I have one suggestion, it is that this well-meaning group consult the China Medical Board or the Rockefeller Foundation before they invest so much money on this type of program.

FAMILIAL RECURRING POLYSEROSITIS

To the Editor:—The editorial in The Journal, June 6, 1959, page 678, entitled "Is Familial Periodic Disease a Nosological Entity?," calls attention to a remarkable disease largely limited to persons of the Armenian, Syrian, or Jewish ethnic groups. In support of this concept of a "nosological entity" we should like to bring attention to our study of 20 such patients, presented before the annual session of the American College of Physicians, April 21, 1959. We have added to the nomenclature of the disease "familial recurring polyserositis." The nomenclature of the disease has had interesting historical deviations. First called a "paroxysmal syndrome" by Janeway and Mosenthal in 1908, it was termed "benign paroxysmal peritonitis" by Siegal in 1945. Reimann included it in his collection of periodic diseases and added "periodic abdominalgia" or "periodic peritonitis."

French authors have objected to the connotation of "periodic," and Siguier in 1953 called the disease "la maladie dite périodique" (so-called periodic disease). The attacks do not always recur regularly but often recur at grossly irregular intervals from a few days to several months. Mamou coined the term "épanalepsie Méditerranéene," meaning recurring Mediterranean attacks. Bickel in Geneva reverted to the eponym of "la maladie de Siegal-Cattan-Mamou." In 1955 Heller in Israel added "familial Mediterranean fever." He has based his *sine qua non* for diagnosis on the attacks of fever. We have observed patients without fever during episodes of severe pain associated with serositis of the peritoneum, pleura, or synovia; hence we object to the use of a physical sign (fever) as the title of this disease. We also object to the implication of a geographical predilection in the title of this disease. The familial predilection is to certain ethnic groups rather than to any geographical area. In Lebanon the disease is called simply "Armenian disease."

Perhaps, in the future, further knowledge of the pathogenesis of the disease may reveal a biochemical concept such as the possible relationship of etiocholanolone to periodic fever as described by Bondy. Meanwhile, it is suggested that the term "familial recurring polyserositis" avoids the pitfalls of naming the disease for a geographical area, or a physical sign, and avoids the erroneous connotation of regular periodicity. On the basis of present knowledge, polyserositis most accurately characterizes the clinical nature of this disease with findings derived from involvement of multiple serous membranes, e. g., peritoneum, pleura, synovia, or meninges. Interestingly, no patients have been reported from America with the renal involvement so prominent in foreign reports. We believe that "familial recurring polyserositis" is an autonomous clinical entity and deserves to be removed from the group of so-called periodic diseases.

URINARY INFECTIONS

To the Editor:—The report by Lattimer and co-workers (The Journal, June 20, p. 938) on the serious problem of urinary infections due to resistant strains of Aerobacter aerogenes merits attention. In considering the use of kanamycin as a preferred method of therapy in such infections, one must bear in mind the reports of impaired hearing that have been attributed to kanamycin (Lustberg, A., and Hamburger, M., *J. A. M. A.* 170:806 [June 13] 1959; Naunton, R. F., and Ward, P. H.; *A. M. A. Arch. Otolaryng.* 69:398 [April] 1959; and Damuth, H., personal communication).

It therefore seems appropriate to direct the attention of the readers of The Journal to the study by Hughes and co-workers (*J. Urol.* 80:75 [July] 1958) in which cycloserine appeared to be "of value in the management of chronic urinary tract infection on an outpatient basis, particularly those infections due to A. aerogenes." However, the use of cycloserine, too, is attended with the risk of toxic reactions, a risk which may be minimized with appropriate regulation of dosage.

MISCELLANY

USE OF HOMOGRAFTS DISPENSED BY CENTRAL ARTERY BANK OF CHICAGO HEART ASSOCIATION

Milton Weinberg Jr., M.D., Evanston, Ill., Egbert H. Fell, M.D., Geza deTakats, M.D.
and
Naomi McElwaine, B.S., Chicago

In August of 1955 the Central Artery Bank of the Chicago Heart Association issued its first lyophilized human vascular segments for transplantation to patients. Under the direction of the cardiovascular surgery committee of the Chicago Heart Association this bank has supplied vascular segments to surgeons throughout the Chicago area for three and one-half years. It is the purpose of this report to review the operations of the Central Artery Bank from Aug. 1, 1955, to Dec. 31, 1958, and to present the results of the use of these grafts in patients.

Three hundred thirty-six homografts have been utilized in patients during this period. All of the vascular segments were obtained at autopsy under carefully controlled conditions. The arteries were sterilized chemically, lyophilized, and stored at room temperature in sealed glass tubes under a vacuum. The methods of obtaining and preparing arterial homografts have been well standardized, and it is not necessary to outline in detail the procedures involved.

With each graft dispensed to a surgeon, a form sheet was attached requesting information regarding the patient, diagnosis, type of operation in which the graft was utilized, and the results of operation. Additional forms were sent to each surgeon at six-month-intervals requesting follow-up information. All expenses of the operation of the Central Artery Bank were borne by the Chicago Heart Association, and the arteries were dispensed without cost to the surgeon, the hospital, or the patient. Special mention is made of the American Red Cross unit in Chicago, which has provided delivery service from the Central Artery Bank to all of the hospitals in which the grafts have been used.

Results in Three Hundred Thirty-six Homografts

The basis of this report is the information obtained from the 38 surgeons in the Chicago area who have used these grafts at operation. The data obtained are presented in categories designated by the type of case in which the graft was used.

Temporary Aortic Cuff.—Fourteen segments of homografts were sutured to aortas to permit inflow from pump-oxygenators and were removed at the end of the procedures, with satisfactory results. None has been used for this purpose since February, 1958, however, and it is likely that the procedure has been discontinued. The principle of using a cuff for access to the aorta may have limited application in certain types of cardiovascular operations.

Roof for Right Ventricle.—One homograft was used for enlarging the right ventricular outflow tract in infundibular stenosis in the period covered by this report. The homograft appears to have certain advantages over the plastic or fabric prostheses for this purpose and will be used in additional similar cases.

Inguinal Hernia Repair.—Two segments of aortic homografts have been used for additional abdominal wall support in two cases of inguinal hernia. The reporting surgeons have indicated that immediate results have been satisfactory and that addition grafts will be used in this manner.

Artery Involved in Tumor.—Three cases of replacement of blood vessels (arteries) involved in tumors have been reported. In two of these cases segments of the abdominal aorta were resected and replaced with homografts. One segment thrombosed one year after operation; the other was reported to be satisfactory at six months, after which the patient was lost to follow-up. In the third case the internal carotid artery was resected and replaced with immediate satisfactory results, but no subsequent reports were received.

Arterial Trauma.—Four cases of resection and replacement with homografts due to trauma to segments of peripheral arteries were reported. Three cases were reported as having satisfactory results with patent grafts up to one year after operation. In the fourth case there was a rupture at the suture line immediately after operation, and the homograft was replaced by a plastic prosthesis.

Superior Vena Cava Obstruction.—Four cases of replacement or bypass of obstructed superior vena cava were reported. In one case of obstruction due to carcinoma, the patient died two weeks after operation. At autopsy the graft was found to be patent and apparently functioning satisfactorily. In each of the remaining three cases bypass of inflammatory strictures of the superior vena cava was carried out. One graft was patent and functioning well one year after operation. One graft remained patent two years, then thrombosed following an accident. The third graft thrombosed three weeks after operation.

Aneurysm of Abdominal Aorta.—Sixty-one cases of resection of aneurysm of abdominal aorta have been reported. In three cases the segments of aorta including the renal arteries were replaced with homografts. These three patients died in the immediate postoperative period of causes unrelated to the grafts.

Seventeen of the patients with aneurysms were operated on as emergencies for acute rupture. Thirteen of the patients died in the immediate postoperative period, three because of disruption of the proximal suture line. It could not be determined whether these three disruptions were associated with defects in the grafts, faulty suturing techniques, or difficulties with the proximal part of the aorta, although the last possibility is perhaps the most likely.

There were 41 resections of aneurysms involving the aorta below the renal arteries; these patients were operated on electively. There were eight deaths unrelated to the grafts, of which seven occurred in the immediate postoperative period and one occurred 12 months after operation. Three deaths were related to the grafts, all occurring in the immediate postoperative period. One of these deaths was due to thrombosis of the graft with extension of the thrombus into the renal arteries. The other two deaths were due to disruption of the proximal suture line.

Of the patients with aneurysms operated on as emergencies, the four surviving patients are well 6 to 16 months after operation. Of the patients operated on electively, 30 are well 6 to 36 months after operation.

Aneurysm of Thoracic Aorta.—Seven cases of resection of aneurysm of the thoracic aorta were reported. Four of these patients died in the immediate postoperative period of causes unrelated to the grafts. Three patients are well more than 24 months after operation.

Aneurysm of Peripheral Arteries.—Nineteen cases of resection of aneurysms of the peripheral arteries were reported.

There was one aneurysm in a vein graft used to replace the femoral artery. This patient is well nine months after replacement with a homograft.

Two aneurysms of the iliac arteries were resected and replaced with homografts. One of these patients died in the operating room of cardiac arrest. The other patient has been well for 18 months since operation. One patient with an aneurysm of the subclavian artery is well 24 months after operation. One patient with an aneurysm of the axillary artery is well six months after operation.

Five aneurysms of the popliteal arteries were resected and replaced with homografts. One graft thrombosed 18 months after operation. One patient died of a myocardial infarction 18 months after operation with the graft functioning well up to that time. Three patients have been well 12 to 18 months since operation.

Ten aneurysms of the femoral arteries were resected and replaced with homografts. Two of the grafts thrombosed, one at one week and one at three months after operation. One graft ruptured at the proximal suture line. There was one wound infection with subsequent rupture at the proximal suture line. Six patients are well six to 24 months after operation with grafts functioning well.

Coarctation of Aorta.—In 22 cases homografts were used in repair of coarctation of the aorta to bridge the resected segments. Two children with preductile coarctations died immediately after operation of causes unrelated to the grafts.

Of 20 cases of postductile coarctations, two patients died in the immediate postoperative period. One patient died of septicemia, with the offending organism being cultured from the graft at autopsy. The second patient died after rupture of the graft at the site of a focus of bacterial endarteritis. The possibility of contamination of these grafts during the processing has been a cause of ever-present concern. However, cultures are taken routinely and since the bank has been in operation not a single positive culture has been returned. The remaining 18 patients are well 6 to 36 months since operation. This group of patients should be especially valuable for long-term follow-up, since all of the patients are children or young adults in good health.

Transposition of Great Vessels.—Partial correction of transposition of the great vessels with grafts from the inferior vena cava to the left atrium was reported in 71 cases. There were 29 deaths in this group, none of which was related to the grafts. The remaining 42 patients are well from a few weeks to 24 months after operation, with the grafts apparently functioning well in all the patients.

Aortic Bypass, Occlusive Disease.—Forty-one cases of aortic bypass for arteriosclerotic occlusive disease were reported. There were five deaths in this group which were unrelated to the grafts. Thrombosis of one or both limbs of bifurcation grafts occurred in 11 cases, from one week to one year after operation. In 25 cases the grafts have been functioning well from 6 to 36 months after operation.

Aortic Resection, Occlusive Disease.—Fifty-five cases of resection of the abdominal aorta for arteriosclerotic occlusive disease have been reported. There were nine deaths in this group, of which five were not related to the graft. The other four deaths were due to thrombosis of the grafts with extension of the thrombi into the renal arteries. Thrombosis of one or both limbs of bifurcation grafts occurred in five cases, four days to 18 months after operation. Forty-one patients in the group are well with functioning grafts 6 to 36 months after operation.

Resection or Bypass, Occlusive Disease of Peripheral Arteries.—Twenty-seven cases of bypass or resection of peripheral arteries for arteriosclerotic occlusive disease were reported.

There were 10 cases of iliofemoral bypass. In six of these cases the grafts thrombosed from one day to one year after operation. One patient was discharged 10 days after operation with the graft functioning well, but was lost to follow-up thereafter. In three patients grafts are functioning well 15 to 36 months after operation.

There were five cases of iliopopliteal or femoropopliteal bypass. In these five patients the grafts thrombosed, 3 to 12 months after operation.

In three patients segments of the femoral artery were replaced with homografts. Two of the grafts thrombosed, 6 and 15 months after operation. In the remaining patient the graft has functioned well 12 months after operation.

Femorofemoral artery bypass was carried out in nine patients. In seven of these patients the grafts thrombosed immediately or up to five months after operation. In the remaining two patients the grafts have been functioning well 6 and 24 months after operation.

The number of arterial homografts used at operation during the individual years is of some interest. In 1955, 23 homografts were implanted into patients; in 1956, 105 homografts; in 1957, 124 homografts; in 1958, 84 homografts. During the last six months of 1958 only 27 homografts were used. This decrease in demand for the homografts, of course, reflects the increasing preference of many of the surgeons for the synthetic grafts. At present, the greatest demand for homografts from the Central Artery Bank is in the partial correction of transposition of the great vessels. For this procedure the synthetics have not proved to be as satisfactory as the homografts.

It is our opinion that the data presented here indicate that the Central Artery Bank of the Chicago Heart Association has fulfilled the purpose for which it was organized in 1955. Special demands for the homografts continue, and as long as a reasonable number of the grafts are utilized the operations of the bank will be continued. Long-range studies on homografts and on the synthetic fabrics are as yet inadequate, and the final dispositions of both types of grafts are not yet determined.

2632 Central Park Ave. (Dr. Weinberg).

STATEMENT OF PRINCIPLES OF ETHICAL DRUG PROMOTION

The Pharmaceutical Manufacturers Association, which was formed in 1958 by the merger of the American Drug Manufacturers Association and the American Pharmaceutical Manufacturers Association, now represents some 140 manufacturers of pharmaceutical products. The board of directors of the Pharmaceutical Manufacturers Association recently adopted the following statement of principles of ethical drug promotion:

We, members of the Pharmaceutical Manufacturers Association, recognizing our responsibilities and obligations to promote the public welfare and to maintain honorable, fair, and friendly relations with the medical profession, with associated sciences, and with the public, do pledge ourselves to the following statement of principles:

1—Prompt, complete, conservative and accurate information concerning therapeutic agents shall be made available to the medical profession.

2—Any statement involved in product promotional communications must be supported by adequate and acceptable scientific evidence. Claims must not be stronger than such evidence warrants. Every effort must be made to avoid ambiguity and implied endorsements. Whenever market, statistical or background information or references to unpublished literature or observations are used in promotional literature, the source must be available to the physician upon request.

3—Quotations from the medical literature or from the personal communications of clinical investigators in promotional communications must not change or distort the true meaning of the author.

4—If it is necessary to include comparisons of drugs in promotional communications, such comparisons must be used only when they are constructive to the physician and made on a sound professional and factual basis. Trademarks are private property that can be used legally only by or with the consent of owners of trademarks.

5—The release to the lay public of information on the clinical use of a new drug or to a new use of an established drug prior to adequate clinical acceptance and presentation to the medical profession is not in the best interests of the medical profession or the layman.

6—All medical claims and assertions contained in promotional communications should have medical preview prior to their release.

7—Any violation of these principles brought to the attention of the President of the Pharmaceutical Manufacturers Association shall be referred by him to the Board of Directors.

These principles were brought to the attention of the Board of Trustees of the American Medical Association at its meeting in Atlantic City. The Board commended the P. M. A. for adopting these principles for ethical drug promotion.

MEDICAL LITERATURE ABSTRACTS

SURGERY

Microscopic Phaeochromocytoma of the Adrenal. P. B. Desai. Indian J. Surg. 21:1-7 (Feb.) 1959 [Madras, India].

The author reports on a 59-year-old man with a microscopic pheochromocytoma in a normal adrenal. The patient was admitted to Tata Memorial Hospital in Bombay, India, because of paroxysmal attacks of headache for one year, unstable blood pressure, pigmentation of the face, and intermittent attacks of vomiting. The blood pressure used to range from 225/135 mm. Hg to 180/100 mm. Hg during the attacks. The basal blood pressure was about 140/80 mm. Hg. An ill-defined round opacity above the left kidney shadow was revealed by a plain roentgenogram of the abdomen. Retroperitoneal pneumography showed a well-rounded shadow, presumably the suspected pheochromocytoma, above the left kidney. The patient was explored by a left-sided thoracoabdominal approach along the 11th rib. Immediate elevation in the blood pressure was observed whenever the left suprarenal area was palpated. A similar manipulation of the right adrenal did not produce any change in the blood pressure. This significant observation led to the decision to remove the left adrenal, although it appeared normal. It was only accidentally discovered that the shadow in the roentgenogram above the kidney region was caused by a cartilaginous patch of thickening on the pleural surface of the diaphragm. The postoperative recovery of the patient was uneventful. The blood pressure showed a sustained drop.

Microscopic examination of the operative specimen showed the distinct contrast between the normal and the tumor tissue of the adrenal. The tumor cells were large with clear cytoplasm, multinucleated, and arranged in cords and sheets, typical of pheochromocytoma. The patient has been followed up for 6 months postoperatively, and he has not had a single attack of headache and rise of blood pressure. His blood pressure now varies from 140 to 160 mm. Hg systolic and from 80 to 90 mm. Hg diastolic. He can, with sufficient reason, be called cured. The significance of sudden elevations of blood pressure, during manipulation of the adrenal gland concerned, in betraying an invisible pheochromocytoma within a seemingly normal and innocuous adrenal, is emphasized. This is a definite indication for removal of that adrenal.

The Treatment of Parosteal Osteoma of Bone. M. M. Copeland and C. F. Geschickter. Surg. Gynec. & Obst. 108:537-548 (May) 1959 [Chicago].

The authors report observations on 22 patients with what they designate as parosteal osteoma, a newly recognized bone tumor which has been designated by others as parosteal osteogenic sarcoma. The new entity occurs in both benign and malignant forms and is seen most frequently in the first 4 decades of life. In 10 of the 22 patients the lesions were found on the posterior surface of the lower femur, bulging into the region of the popliteal space. Similar growths were observed about the upper femur, upper and lower portions of the humerus, upper ulna and radius, upper fibula, and lower tibial regions. The group of patients included 12 females and 10 males. A swelling or mass and local pain or tenderness were the outstanding clinical features. Ten of the patients had noticed a mass for one year or more. One patient had noticed an increasing enlargement of her lower thigh for 7 years. In one patient, irradiation for skin disease preceded the bone lesion by 32 years.

On examination, a mass of bony hardness is felt, which is firmly attached to the adjacent bone. The periphery of the bony mass is usually smooth in contour. On roentgenologic examination, a mass, densely ossified, circumscribed, frequently sharply outlined, and occurring outside the bone but contiguous with it, is usually visible. At operation, the mass is found fused with the periosteum, with pseudoencapsulation often seen at its outer margins. Grossly, on section, the tumor has a firm, dry, striated surface much like fibrosed cancellous bone. Microscopically, although adult bone and fibrous tissue predominate, foci of cartilage cells may be seen. At the periphery the growths are more apt to show increased cellularity and, in a number of cases, have shown features of fibrospindle-cell sarcoma.

Of the 22 cases reviewed, 16 had been previously described by the authors. Observations on these and on 6 new cases emphasize the fact that paros-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

teal osteomas are potentially malignant lesions. The original lesion appeared to be benign in 14 of the 22 patients. Subsequent surgery, necessary for recrudescence, revealed the tumor as benign in only 2 cases at the second operation. The tissue removed in the only or final operation was considered malignant in 15 instances, benign but cellular in 3, and typically benign in 4. Of 18 patients with determinate reports, 11 are living and well 5 or more years after resection (excision) or amputation. Eight of these patients are living and well for from 7 to 25 years after treatment, while 3 lived 5 or more years and then died of metastases. In 8 of 13 patients the disease recurred after local excision or resection, and amputation was necessary. Five of the 8 patients died of their disease, while 3 are living and well after 5 years or more. Three primary amputees are 5-year survivals, without disease.

Ablative surgery by resection or amputation is necessary to cure parosteal osteoma, in the majority of cases. If complete resection in a relatively inactive lesion can be accomplished, cure should result. There is no place for temporizing surgical excisions. If there is any question about adequate en bloc resection, then amputation is indicated. When pathological changes show frank sarcoma, amputation is indicated at once. Recurrent cases, with or without malignant manifestations, are best treated by amputation. Parosteal osteoma must be differentiated from (1) localized myositis ossificans, (2) intraligamentous osteoma or osteoma of the tendon sheath, (3) sclerosing osteogenic sarcoma, and (4) osteochondroma and exostosis. The differentiating features are discussed.

Observations on Hepatitis Associated with Biliary Lithiasis: Histopathological and Clinical Studies on 90 Cases. B. Kourias and N. Papacharalampous. Lyon chir. 55:179-190 (March) 1959 (In French) [Paris].

The authors carried out histopathological studies on liver specimens obtained from 90 patients who had undergone surgery (87 for cholecystitis, with or without lithiasis, and 3 for duodenal ulcer); the object was to find out whether alterations had taken place as a result of the primary disease. The histological examinations were made on both superficial and deep liver specimens obtained by aspiration biopsy. The findings of these examinations showed that there were neither superficial nor deep lesions in 6.9% of the patients, but both superficial and deep lesions were found in 48.8% of the patients. The lesions were severe in 22.7%, moderate in 54.5%, and mild in 22.7%. The deep lesions were much less severe than the superficial ones in 26.6%. The lesions were localized exclusively in the superficial region in 18.6%. Thus, lesions have been found either in the hepatic cells or in the interstitial tissue, or in both, in 93.1% of the patients. The deep lesions should be considered more important than the frequently occurring lesions of the liver cortex. The most serious lesions were noted in patients with jaundice, but no correlation could be established between the duration of the disease and the seriousness of the lesion. A marked inconsistency was observed between the liver function tests in these patients and the extent of the hepatic lesions.

There were 2 deaths. The rest of the patients were followed up for from 1 to 3 years; the results were generally satisfactory even in those who had had severe hepatic disease. This study warrants the conclusion that cholecystectomy or concurrent drainage of the common bile duct will lead to regression of the hepatic lesions in most patients.

Acute Arterial Occlusion of Extremities: Study of 20 Cases. H. M. Coelho, J. Fernandes Oliveira and P. M. Garcia. Rev. paulista med. 54:167-176 (March) 1959 (In Portuguese) [São Paulo, Brazil].

Twenty patients with acute peripheral arterial occlusion were observed during 1957 at the Faculty of Medicine of the University of São Paulo. Observations were made either until death or for more than a year after discharge from the hospital. The period of time which elapsed between the appearance of occlusive symptoms and hospitalization varied between 2 hours and 7 days in 19 patients; in one patient, however, it was 5 months. The occlusion was caused by an embolus in 18 patients, by repeated arterial trauma during intra-arterial blood transfusion in one, and by a dissecting aneurysm of the aorta and right iliac artery in one. Most of the patients who had had rheumatic fever developed embolism between the ages of 40 and 50 years, whereas those with hypertension, arteriosclerosis, and myocardial sclerosis developed it between 55 and 82. The occluded arteries were the axillary in 4 cases, brachial in 3, iliac in 4, femoral in 5, and popliteal in 2, as well as the bifurcation of the aorta in 5. The total number of involved limbs was 28, because of the presence of bilateral or multiple emboli in some cases. Most of the patients were hospitalized in grave condition. Two entered in coma, with severe cardiac disease, multiple embolism, and the legs in cadaveric rigidity; they died of cerebral embolism 5 and 24 hours, respectively, after hospitalization. In the remaining 18 patients there was acute or moderate ischemia in 11 limbs, muscular induration in 5, necrosis in 1, and gangrene in 4. Preoperative treatment consisted of drugs to correct heart decompensation, shock, anemia, dehydration, and decompensated diabetes.

Seven patients had an embolectomy, and arterial circulation was reestablished in the limbs of 5, since the operation was performed within 8 hours after the appearance of occlusive symptoms. An amputation was performed in the case of 3 patients with gangrene; 2 of these patients died. Conservative treatment, consisting of sympathetic blockage and intravenous injections of heparin in doses of 75 or 100 mg. at intervals of 4 hours, was given to 8 patients, with good or fair results in 6; in the remaining 2 patients the treatment was followed by the appearance of gangrene, which called for amputation. Of the 20 patients in this series, there was an operative mortality from embolectomy or amputation in 4 patients, and death occurred as a result of embolism or gangrene in 7. Nine patients are surviving in a satisfactory or fair condition one year after discontinuation of the treatment. The best results were obtained in those who were treated not later than 8 hours after the appearance of occlusive symptoms.

Needle Biopsy of the Liver During Abdominal Surgery. R. B. Terry. Am. J. Digest. Dis. 4:378-388 (May) 1959 [New York].

The author describes an instrument which has been found suitable for needle biopsy of the liver during abdominal surgery. In patients with abdominal carcinoma in whom hepatic nodules are found, liver biopsy becomes imperative. Such hepatic nodules are often difficult to assess by inspection and palpation. In a proportion of cases unnecessarily palliative surgery may be performed, and gross errors in prognosis made, if hepatic nodules are not examined histologically. Biopsy of the liver by wedge resection during abdominal surgery is occasionally attended with difficulty and may fail to obtain satisfactory tissue because of the atypical nature of the free margin of the liver; for these and other reasons, it is frequently not performed when indicated. Needle biopsy of the liver during abdominal surgery is simple and rapid; any bleeding is easily controlled, and the specimen obtained is not only adequate in size but contains fewer artefacts than that obtained by wedge resection. The author performed 35 biopsies with the biopsy instrument during abdominal surgery. The material proved to be adequate for diagnosis. There was no difficulty in controlling bleeding, which in many instances was remarkably slight, and no complications were encountered in the series. The mortality rate for "medical" or percutaneous biopsies of the liver has been 0.12% among 10,600 biopsies reported in the literature, while the incidence of significant complications has been 0.38%. There would presumably be far less trouble with needle biopsy of the liver performed during abdominal surgery.

GYNECOLOGY & OBSTETRICS

Endometriosis Involving the Pleura. C. B. Ripstein, M. Rohman and J. B. Wallach. J. Thoracic Surg. 37:461-471 (April) 1959 [St. Louis].

The authors report on a 24-year-old woman with endometriosis involving the pleura. The patient had recurrent hemorrhagic effusion, increased menses associated with moderate abdominal pain, and inability to conceive. The diagnosis was considered clinically and was confirmed by histological examination of tissue from the pleural and peritoneal cavities. Diagnostic pneumoperitoneum was followed promptly by pneumothorax, indicating the presence of a communication between the pleural and peritoneal spaces on the right and permitting the application of the implantation theory in explanation of this unusual site of endometriosis. The cases of only 2 patients with pleural endometriosis and 1 with endometriosis of the lung have so far been reported in the literature. This pathological process should be considered in a young woman with recurrent hemorrhagic pleural effusion of obscure etiology. Early treatment directed at suppression of ovarian function will provide relief of the debilitating symptoms secondary to the continuing accumulation of the irritating bloody fluid in the pleural space.

Combined Radiologic-Surgical Treatment of Carcinoma of the Cervix. T. Dahle. Surg. Gynec. & Obst. 108:600-604 (May) 1959 [Chicago].

The author believes that both irradiation and surgical treatment have a place in the therapy of carcinoma of the uterine cervix. This study was undertaken to investigate the anatomic spread of cancer of the uterine cervix in patients with stage 1 lesions, and to analyze the dangers to the ureters in combined radiologic and surgical treatment. Two hundred sixty-six patients with stage I cervical cancer were admitted to the Norwegian Radium Hospital in Oslo in 1954, 1955, and 1956. For various reasons it was not possible to perform radical surgery on all these stage 1 patients and only 96 of them underwent radical surgery and preoperative radium treatment. The material was a selected one, the patients being young and in relatively good condition. The clinical staging was always made under Nembutal anesthesia and the examination of the renal tract always included urinalysis, determination of the blood urea, cystoscopy, and urography. There were 88 cases of squamous- carcinoma and 1 of adenocarcinoma; in 7 cas diagnosis was undifferentiated carcinoma.

All the patients first received radium equivalent to from 6,000 to 7,200 mg.-hr fractions (30 mg. of radium in the va to 30 mg. in the uterus for 5 days selected for combined therapy were teal osteomas are potentially malignant lesions. The original lesion appeared to be benign in 14 of the 22 patients. Subsequent surgery, necessary for recrudescence, revealed the tumor as benign in only 2 cases at the second operation. The tissue removed in the only or final operation was considered malignant in 15 instances, benign but cellular in 3, and typically benign in 4. Of 18 patients with determinate reports, 11 are living and well 5 or more years after resection (excision) or amputation. Eight of these patients are living and well for from 7 to 25 years after treatment, while 3 lived 5 or more years and then died of metastases. Early treatment directed at suppression of ovarian function will provide relief of the debilitating symptoms secondary to the continuing accumulation of the irritating bloody fluid in the pleural space.

Combined Radiologic-Surgical Treatment of Carcinoma of the Cervix. T. Dahle. Surg. Gynec. & Obst. 108:600-604 (May) 1959 [Chicago].

The author believes that both irradiation and surgical treatment have a place in the therapy of carcinoma of the uterine cervix. This study was undertaken to investigate the anatomic spread of cancer of the uterine cervix in patients with stage 1 lesions, and to analyze the dangers to the ureters in combined radiologic and surgical treatment. Two hundred sixty-six patients with stage 1 cervical cancer were admitted to the Norwegian Radium Hospital in Oslo in 1954, 1955, and 1956. For various reasons it was not possible to perform radical surgery on all these stage 1 patients, and only 96 of them underwent radical surgery and preoperative radium treatment. The material was a selected one, the patients being young and in relatively good condition. The clinical staging was always made under Nembutal anesthesia, and the examination of the renal tract always included urinalysis, determination of the blood urea, cystoscopy, and urography. There were 88 cases of squamous-cell carcinoma and 1 of adenocarcinoma; in 7 cases the diagnosis was undifferentiated carcinoma.

All the patients first received radium treatment equivalent to from 6,000 to 7,200 mg.-hr. in 1 or 2 fractions (30 mg. of radium in the vagina and 20 to 30 mg. in the uterus for 5 days). The patients selected for combined therapy were discharged 1

6 to 8 weeks and then readmitted for radical hysterectomy and pelvic lymphadenectomy. The patients not selected for the combined treatment, immediately after the radium treatment, underwent a complete course of x-ray therapy, including a 3,000-r skin dose to each of 2 anterior and 2 posterior pelvic ports. It is known that the clinical staging of patients with carcinoma of the cervix is often unreliable, and such was the case in this material. In 18 of the 96 supposedly stage 1 patients, metastases were found in the lymph nodes. Since Meigs found lymph node invasion in 17.5% of stage 1 patients treated only surgically, it appeared that radium therapy had no influence on the lymph node metastases. In 16 of the 96 patients, residual carcinoma was found in the cervix, but in 12 of the 18 patients with lymph node metastases, no residual carcinoma was found in the cervix.

No rectovaginal or vesicovaginal fistula resulted, but, when possible, damage to the ureters was examined by means of urography; 69 patients showed no abnormality from 6 months to 1 year after treatment, but 22 did show damage. Four patients are now dead, 3 having died of carcinoma and 1 of bilateral pyonephrosis. It is believed that most of the changes in the urinary tract were caused by the treatment, but in 11 of the patients the hydroureter or hydronephrosis was slight. The possibility of damage to the urinary tract must be borne in mind when reflecting on the value of the combined radiologic and surgical treatment.

Association of Cervical Cancer with Circumcision of Sexual Partner. J. E. Dunn Jr. and P. Buell. J. Nat. Cancer Inst. 22:749-764 (April) 1959 [Washington, D. C.]

There have been reports to the effect that cervical cancer is only one-fifth or less as frequent in Jewish women as in non-Jewish women. Wynder and associates in 1954 reported on data from 2 sources in support of the hypothesis that circumcision of the male is a protective factor. The present authors suggest that other factors might be involved. They present data from a study not designed solely to test the question of circumcision but to study other variables possibly associated with cervical cancer. During the years 1951-1955, 429 patients with cervical cancer were interviewed. The same number of controls were selected by matching on age (within 5 years), race, ever married, and ever parous. A further restriction was made by selecting the patient-control pair from the same hospital (Los Angeles County Hospital) or the same private or group practice. Attention is called to differences in the collection of controls by Wynder. The present authors in their interviews were unable to find an association between having cervical cancer and reporting an uncircumcised husband. Wynder had previously reported an association in a study that also used data on circumcision history obtained from interviews with women patients. There may have been differences in asking the questions about circumcision, but, if so, it is not clear how the data were affected.

An additional independent investigation of circumcision as an anatomic fact revealed that Jewish men probably have a maximum degree of anatomically complete circumcision, which occurs in less than half of non-Jewish men who consider themselves circumcised. The circumcision study also revealed that one-fourth to one-third of men naturally may have a partially shortened foreskin, which is similar to that of some men who have been circumcised, but, in an interview study, many of them will be counted as uncircumcised. Consequently an interview study of non-Jewish subjects may fail to identify the fully circumcised and further dilute the results with many "partially circumcised" classified as uncircumcised. Possibly the problem can be settled only in a study which makes direct examinations of sexual partners to distinguish full and partial circumcision.

The Occurrence of Episodes of Immunization in Pregnancy Associated with Rh Haemolytic Disease of the New-Born. G. A. Kelsall, G. H. Vos and R. L. Kirk. M. J. Australia 1:488-493 (April 11) 1959 [Sydney].

The authors carried out antenatal titrations of antibodies found in pregnant mothers, serums at the King Edward Memorial Hospital for Women in Subiaco, Western Australia, at every available opportunity during the last 7 years. Frequent titrations in the course of pregnancy showed that immunization of the mother occurs as one or more episodes during the pregnancy, and that the resulting antibody titers may be of minor or major magnitude. The prognosis for the fetus depends largely on the Rh-antibody titer. The patterns of antibody behavior were numerous and varied. The findings seem to justify the following conclusions concerning the prognosis for a particular pregnancy and the outlook for later pregnancies. 1. A previously immunized woman may undergo a further incompatible pregnancy without any episode of immunization occurring in the later pregnancy. If the initial titer in such a pregnancy is low, the infant will be mildly affected; if the initial titer is high, the infant may be severely affected. 2. A previously immunized woman may have one or more episodes of immunization in a subsequent incompatible pregnancy. The outcome for the fetus will depend on the number of episodes, the rise of titer, and the duration of a high titer of antibodies. 3. Antibody titers may fall between pregnancies, and sufficient time must be allowed for this to happen. A sensitized woman mated to a homozygous man has a much better chance of having a surviving infant if her titer is low at the beginning of pregnancy.

Antibodies frequently appear for the first time in the last 4 weeks of pregnancy, and they may rise precipitiously to lethal levels in the few remaining weeks of pregnancy. Of 409 immunized mothers, 75 (18%) were free of antibodies when first examined by the authors; antibodies developed in 33 (8%) before 34 weeks of gestation had been completed, and in 42 (10%) antibodies developed after this time. Of the 334 (72%) who already had antibodies when first examined, 113 (25%) had an episode of immunization before 34 weeks, and 196 (45%) had one after 34 weeks' gestation. The premature induction of labor at 36 weeks probably obviated the occurrence of many more dangerous episodes in the last 4 weeks of pregnancy. Induction of labor is not only of value in that particular pregnancy, but must have some bearing on the success of future pregnancies, in that it would tend to keep the mother's titer at a lower postconfinement level and provide a lower antibody "take off" when the next pregnancy begins.

Wertheim Hysterectomy in the Treatment of Endometrial Carcinoma. L. Parsons and F. Cesare. Surg. Gynec. & Obst. 108:582-590 (May) 1959 [Chicago].

In view of the renewed interest in radical dissection of the pelvic lymphatics for cervical cancer, the authors elected to employ the Wertheim type of hysterectomy and pelvic node dissection in the treatment of endometrial carcinoma. This report, based on 62 cases in which treatment consisted of the Wertheim hysterectomy, is presented as a critical study of the many factors underlying the management of endometrial carcinoma by a radical surgical approach. The patients were observed at several hospitals in the area of Boston between 1946 and 1956. There were 52 adenocarcinomas, 9 adenoacanthomas, and 1 carcinosarcoma. Fifty-two were primary cases, while in 10 previous irradiation had been received. Myometrial invasion was present in 37 cases, or 60% of the group. Bilateral pelvic lymph node dissection was carried out in 50 of the 62 patients, while in the remaining 12 no pelvic lymph node dissection was done. Lymph node involvement was observed in 4 of the 50 patients in whom the nodes were dissected, and these 4 belonged to the group of 37 who had myometrial invasion. One of the 4 women died in the hospital, 1 lived 3 years, and 2 are alive and well at 2 years. Complications occurred in 27% of the patients, urinary tract disturbances accounting for 12% of these. Urinary fistulas developed in 5 patients, an incidence of 8%. Etiological factors as well as practical preventive measures are discussed. There was one surgical death (1.6%).

The technique of the Wertheim hysterectomy is briefly described. Of 3 pelvic recurrences, 2 appeared within the first year, but the third not until 3 years after the operation. This latter case is of special interest, having shown both myometrial and lymph node involvement. Two of these patients ultimately died of their disease, while the third is still living and well 6 years after vaginectomy. The 5-year survival can be evaluated in 33 of the 62 patients. Twenty-six of the 33 patients survived 5 years or more without recurrence, an absolute 5-year cure rate of 78%. Two patients are now alive and well 10 years after surgery. The 5-year survival of the primary treatment group was 81% (22 of 27 patients). In the patients with myometrial invasion the 5-year salvage rate was 71%.

The authors feel that the results obtained compare favorably with those reported in the current literature and justify further evaluation of the radical surgical approach for the treatment of endometrial cancer. The high incidence of postoperative complications, however, imposes heavy obligations on those who treat and care for these patients. It is hoped that future experience and observations will add to the knowledge of the metastatic spread of endometrial cancer, improve selection of patients, and reduce morbidity, at which time the Wertheim hysterectomy with pelvic lymph node dissection may prove worthy of more routine use.

Early Cancer Detection: Prediction of Preclinical and Preinvasive Stages by Cytology. J. E. Ayre. Acta Unio internat. contra cancrum 15:289-295 (no. 2) 1959 (In English) [Louvain, Belgium].

In the diagnosis of early preclinical cancer, cell scraping is the method of choice for the collection of material. In examinations on 111,963 patients, 1,874 gynecologic cancers (20.3%), were found by cytology, and 59 were missed, including 22 cervical cancers. Absence of clinical symptoms is inadequate in discarding cancer diagnosis. Comparisons of clinical appearance and cytological findings are presented for preinvasive, early invasive, and infiltrating cancers. Among 347 histologically confirmed cancers, 70 were "cytologically early"; cytological diagnosis of preinvasive nature was confirmed in 70% of the cases. Cell-population studies allowing this diagnosis are discussed.

PEDIATRICS

Sequestration of the Lung. M. C. Buchanan. Arch. Dis. Childhood 34:137-139 (April) 1959 [London].

The author reports on a girl with an abnormal pulmonary artery supplying a sequestrated segment of the lung, who at the age of 8 years was admitted for the first time to the Queen Elizabeth Hospital for Children in Londan for vague symptoms of ill health, such as tiredness, occasional headaches, pain in the limbs, and cough. A chest roentgenogram did not show any evidence of a pulmonary lesion except basal emphysema on both sides. At the age of 11 years the patient was again admitted to the hospital for similar symptoms. In addition, her temperature was 103 F (39.4 C). A chest roentgenogram showed a partial collapse of the right middle lobe and the anterior segment of the lower lobe. Sulfonamide and penicillin therapy was ineffective in controlling the symptoms and the pyrexia. Improvement resulted from treatment with chlortetracycline (Aureomycin), and serial chest roentgenograms showed some resolution of the lesion at the right base, but a tomogram showed cyst-like cavitation in the periphery of the right lower lobe, irregular consolidation, and thickening of the bronchial wall.

After 13 weeks in the hospital, the patient was discharged, only to be readmitted 3 weeks later with anorexia, recurrence of cough, and a temperature of 100 F (37.8 C). A bronchogram was obtained, revealing a lesion whose behavior, site, and appearance suggested a sequestrated lung segment. Excision of the right lower lobe was performed. There was a small mass in the posterior basal segments. Entering this mass from the region of the diaphragm was a vessel about 3 mm. in diameter. Microscopic examination of the operative specimen revealed a small abscess cavity in the posterior subapical area. In the posterior basal region there was an area of lipid pneumonitis containing a number of small abscesses. In the anteromedial portion of the lobe there was a tube-like structure which extended laterally and divided into a number of branches; this was thought to be an ectopic bronchus. Moreover, there was emphysema of the basal segments. After the operation the patient made a complete recovery.

The syndrome of sequestrated lung segment is probably not as rare as is generally believed. The condition is disabling, but it is cured by surgery. There are few symptoms referable to the lungs, minimal physical signs, but gross roentgenologic changes. The condition, once suspected, can be diagnosed before operation. The most likely explanation of its causation in the patient reported is that there was a small communication between the air contained in the surrounding normal lung and the air spaces in the ectopic tissue; this was sufficient to aerate the latter, but it was insufficient to drain the products of infection once the condition had occurred.

Treatment of Diphtheria with Terramycin. H. W. A. Voorhoeve. Maandschr. kindergeneesk. 27:119-132 (April) 1959 (In Dutch) [Leiden, Netherlands].

The incidence of diphtheria has decreased in the Netherlands in recent years, and this has been ascribed to the fact that more children are being vaccinated against it. The mortality of diphtheria, however, has remained about the same, namely, 6%. This persisting high mortality induced the author to evaluate the treatment of diphtheria. He compared 2 groups of 55 patients each, one being treated before 1953 and the other after 1953. The diagnosis was bacteriologically verified in both groups of patients. All were treated with the same type of antidiphtheria serum, which was administered by intramuscular injection in doses of from 20,000 to 40,000 units.

On the basis of a 1953 report by Lall and Karelitz, of New York, on the use of Terramycin in diphtheria (abstracted, J. A. M. A. 153:592 [Oct. 10] 1953), the administration of Terramycin, in addition to antidiphtheria serum, was begun at the Juliana Kinderziekenhuis (Den Haag) in October, 1953. Terramycin was given in daily doses of 50 mg. per kilogram of body weight, divided into 3 or 4 doses, usually by mouth. While the addition of Terramycin to the treatment produced no noticeable change in the mortality from diphtheria, throat cultures became more rapidly negative, so that the children did not have to remain isolated for such a long period and hospitalization could be shortened. On the other hand, it seems probable that with Terramycin therapy the immunizatory effect of the diphtheria is lessened, and so the author feels that patients who have received Terramycin for diphtheria should still be immunized against the disease.

The Antibiotic Management of Staphylococcal Disease in Infants and Children. M. D. Yow, M. M. Desmond and L. N. Nickey. South. M. J. 52:392-400 (April) 1959 [Birmingham, Ala.].

The authors report on 155 infants, aged less than 2 months, 32 babies, between the ages of 2 months and 2 years, and 17 older children, all with staphylococcic infections who were treated with antibiotics at Jefferson Davis Hospital in Houston, Texas, between 1956 and 1958. Eighty per cent of the staphylococcic infections were classified as hospital-acquired, and 20% were considered to be of extra-hospital origin. Sixty-six of the 204 patients had mild disease, and 138 had moderately severe or severe involvement. The antibiotic agents employed were selected on the basis of probability of response until the results of in vitro testing were available. During the first year of this study most of the patients with hospital-acquired infections were treated with a combination of erythromycin and streptomycin, erythromycin and chloramphenicol or chloramphenicol or novobiocin alone (bacteriostatic antibiotics). Disappointing results with these commonly used antibiotics and increasing awareness that a large proportion of these infections were due to the virulent Staphylococcus organisms phage-type 81, led to a trial of bacitracin and kanamycin (bactericidal agents). Both these drugs seemed especially suitable for use in infants and children because of their bactericidal activity and because they could be administered by the intramuscular route. In seriously ill patients all antibiotics were given initially by the parenteral route for a minimal period of 48 hours. Oral therapy was used when the patient began to improve and where it was practical. Local administration of antibiotics was used in localized infections, such as empyema, purulent pericarditis, meningitis, and septic arthritis.

The age of the patients influenced morbidity and mortality. Among the 138 patients with serious staphylococcic disease, the mortality rate was 43% in the premature infants, 26% in the full-term newborn infants, 21% in children from 2 months to 2 years of age, and 12% in older children. The degree of dissemination was related to the age of the patient, demonstrating inadequacy of host defenses in the young infant. The selection of the specific antibiotic agent for the treatment of staphylococcic disease, including impetigo, conjunctivitis, subcutaneous abscess, septicemia, pneumonia, gastroenteritis, meningitis, and miscellaneous conditions, depends on the age and condition of the host. In older children or patients with normal defense mechanisms, mild and moderately severe staphylococcic infections can be expected to respond to treatment with bacteriostatic antistaphylococcic drugs. Controlled studies are needed to establish the best method of management of mild superficial infections in the newborn infant. Even moderately severe infections in the young infant must be considered potentially dangerous because of the infant's inability to localize infection, and this patient should be treated with a bactericidal antistaphylococcic drug. The prognosis of severe staphylococcic disease in all age groups is so grave that intensive therapy with a bactericidal antibiotic or a combination of a bactericidal drug and a bacteriostatic drug is indicated.

Nephrocalcinosis Infantum. R. A. Shanks and A. M. MacDonald. Arch. Dis. Childhood 34:115-119 (April) 1959 [London].

The authors report on 84 cases of nephrocalcinosis observed in children who died at the Royal Hospital for Sick Children in Glasgow and on whom autopsies were performed between 1928 and 1957. Nine cases were observed between 1928 and 1937, 15 between 1938 and 1947, and 60 between 1948 and 1957; these data suggest a true increase in the incidence of this condition. Of the 9 cases, 3 occurred in infants aged less than 1 year, 1 in an infant between 1 and 2 years, and 5 in children over 3 years of age. Of the 15 cases, 9 occurred in infants aged less than 1 year, 3 in children between 1 and 3 years, and 3 in children over 3 years of age. Of the 60 cases, 47 occurred in infants aged less than 1 year, 10 in infants between the ages of 1 and 2 years, and 3 in children over 3 years of age. Thus, 70% of the cases were observed in infants in the course of the first year of life.

A wide variety of pathological conditions, in themselves sufficient to cause death, was found in association with the lesions of nephrocalcinosis in this series of patients. The first and most obvious explanation for these findings is that nephrocalcinosis is a casual autopsy finding seldom related to the cause of death. The virtual absence of the condition in children between 2 and 3 years of age likewise suggests that not only is it usually not fatal but it normally proceeds to complete resolution. The implications, therefore, are that most of the lesions of nephrocalcinosis belong to a benign disorder of infancy without severe symptoms and with an excellent prognosis. The condition is probably related to idiopathic hypercalcemia of infancy.

OPHTHALMOLOGY

The Treatment of Iris Melanoma. A. B. Reese and G. W. Cleasby. Am. J. Ophth. 47:118-125 (May) 1959 [Chicago].

This report is based on 157 cases of melanoma of the iris. They include (1) patients seen and treated at the institute of ophthalmology, Columbia-Presbyterian Medical Center, New York, and Stanford University Hospital, San Francisco; (2) patients seen in consultation by members of the staff of the institute of ophthalmology but treated elsewhere; and (3) patients operated on elsewhere, whose tumor specimens or sections were sent to the pathology department of the institute of ophthalmology for opinion. From the standpoint of treatment the 157 patients fall into the following 3 groups: (1) those that had excisional iridectomy (63); (2) those that had enucleation (72); and (3) those that were observed (22). Patients in the third category were those who were thought to have a probable malignant melanoma based on clinical appearance and behavior but who either refused operation or were not urged to have surgery.

Any pigmented iris lesion showing progressive growth or other evidence of malignant behavior should be excised by means of iridectomy if it seems possible to remove it completely in this manner. A lesion located in the periphery of the iris should be excised early, since any growth would be likely to involve the angle and ciliary body. Enucleation is advisable if the tumor has obviously spread beyond the reach of local excision or there is evidence of residual tumor peripheral to a previously performed iridectomy. The pathological diagnosis of malignant melanoma does not provide grounds for enucleation in the absence of microscopic and/or clinical evidence of remaining tumor. Observation is necessary in any case in which there is not clear-cut evidence of malignant character or behavior, and there are no other indications for surgery.

The over-all mortality in this series, as in other groups reported, was quite low. There were 4 known deaths due to metastatic spread in the 140 cases with follow-up information. Altogether, 60 cases have been followed for 5 years or longer, and 120 cases for 2 years or longer. Of great importance is the fact that no deaths occurred in patients receiving excisional iridectomy as the definitive therapy. It is evident that an iridectomy performed properly at a time when all the tumor can be removed in this manner not only prevents metastatic involvement but avoids the late complications of secondary glaucoma, pain, and blindness which can result from local dissemination. Analysis of the 4 fatal cases shows that enucleation was ultimately performed in each instance. In all these cases microscopic study revealed that the tumor had spread beyond the reach of local excision. In 2 cases excisional biopsies were performed 6 days and 1 week, respectively, prior to subsequent enucleation. In the third case, iridectomies were performed in the course of 2 trephining operations during a 5-month period prior to enucleation, when it was ultimately recognized that the glaucoma present was secondary to a diffuse melanoma of the iris. In the fourth case enucleation was performed without initial iridectomy.

External Ophthalmoplegia as Part of Congenital Myasthenia in Siblings: Myasthenia Gravis in Children: Report of a Family Showing Congenital Myasthenia. F. B. Walsh and W. F. Hoyt. Am. J. Ophth. 47:28-34 (May) 1959 [Chicago].

The authors describe observations on 4 boys with congenital myasthenia and external ophthalmoplegia, who belonged to a family of 6 children in which the parents and 2 daughters were normal. They discuss the various types of myasthenia in children, pointing out that congenital myasthenia is a term used by Levin to describe a form of myasthenia which begins at birth (or before) and is characterized by a mild onset, marked external ophthalmoplegia, partial ptosis, and symmetrical weakness of involved muscle groups. It may be associated with marked weakness of skeletal muscles, especially neck, trunk, and leg muscles. In contrast to the usual form of myasthenia gravis, it is not progressive, does not have remissions, and may improve with time, the response to Prostigmin being dramatic. This disease occurs in siblings without involvement of the parents and is variable in severity. Levin feels that it is not the myasthenia gravis described by Erb and Goldflam, though the basic defect (dysfunction at the myoneural junction) is the same or at least is similar.

The 4 cases presented by the authors closely resembled those described by Levin. Partial ptosis and almost total external ophthalmoplegia were the outstanding findings. One member of this family had severe generalized weakness and fatigability of his skeletal musculature, which was symmetrical and which showed neither remissions nor improvement with time. The response to Prostigmin, though, was dramatic. The use of Prostigmin and electromyography is urged in the differential diagnosis of congenital external ophthalmoplegia.

Arcus Senilis: Its Pathology and Histochemistry. D. G. Cogan and T. Kuwabara. A. M. A. Arch. Ophth. 61:553-560 (April) 1959 [Chicago].

Arcus senilis consists of a peripheral corneal opacity that depends on the presence of proximal blood vessels but yet spares the immediate surroundings of the blood vessels. While present to some extent in all persons past middle age, an arcus is also present occasionally in young persons and is particularly common in persons with familial hypercholesteremia and xanthomatosis. A histological study of 25 eyes obtained through the facilities of the Boston eye bank revealed that arcus senilis is characterized by a hyaline sudanophilia of Descemet's and Bowman's membranes and a granular sudanophilia of the corneal stroma. It is invariably associated with a similar sudanophilia of the anterior sclera. The sudanophilia of Descemet's membrane is noteworthy in that it tends to spare the most peripheral portion of this membrane, and, in its early stages, it involves preferentially the anterior half of this membrane in the form of double laminas. The sparing of the limbus is apparently due to the vascularity of this region. Histochemical and solubility studies of sections from these eyes were performed with the purpose of identifying the fat of arcus senilis. It appeared to be a mixture of cholesterol, phospholipid, and neutral fat. The facts that it may be present in relatively massive amounts, and that it does not depend on any degenerative change in the cornea, suggest that it is derived from the blood and becomes secondarily bound to the tissue. The authors, though, were unable to induce any similar binding in vitro by a comparable mixture of lipids from egg yolk.

THERAPEUTICS

Effect of Drugs on Motion Sickness Produced by Short Exposures to Artificial Waves. E. M. Glaser and R. A. McCance. Lancet 1:853-856 (April 25) 1959 [London].

The authors tested the effectiveness in the prevention or treatment of motion sickness of 4 drugs, hyoscine hydrobromide (in doses of 1 mg.), cyclizine hydrochloride (in doses of 50 mg.), meclizine hydrochloride (in doses of 25 mg.), and perphenazine (in doses of 8 mg.), as well as a lactose placebo; the subjects were 77 soldiers, between the ages of 19 and 25 years, who volunteered for the tests. For an hour after the capsules containing the drugs had been taken, the persons tested were exposed to motion in inflatable tended rubber floats, the position of which in an experimental tank varied from test to test. While exposed to wave motion, the persons were asked to sit up in order to have constant and maximal stimulation of the vestibular apparatus. In the cross-over-double-blind experiment, hyoscine hydrobromide gave significantly better protection against sea sickness than the other treatments. Cyclizine (Marezine) hydrochloride provided somewhat better protection than the undistinguishable lactose placebo. Two commercial preparations of meclizine hydrochloride, Ancolan and Bonamine, as well as perphenazine (Trilafon), were not more effective than the lactose placebo. In single exposures, the lactose placebo appeared to provide significant protection from motion sickness when compared with the effects of no treatment at all. Divergent findings in different experiments could be explained by the possibility that the apparent effects of drugs against motion sickness are sometimes due to psychological reasons, and that the effects of treatment could also be related to the varying susceptibilities of the persons to motion sickness.

Experiences with Isolation-Perfusion Technics in the Treatment of Cancer. O. Creech Jr., E. T. Krementz, R. F. Ryan and others. Ann. Surg. 149: 627-640 (May) 1959 [Philadelphia].

In an attempt to administer effective amounts of cancericidal agents and at the same time reduce the danger of systemic toxic effects, the authors developed the isolation-perfusion techniques for the treatment of malignant lesions. These techniques consist in excluding the tumor-bearing area from the systemic circulation and perfusing it with a chemotherapeutic agent. For tumors on the foot and leg without evidence of inguinal spread, perfusion is accomplished through the common femoral artery and vein. For perfusion of lesions of the hand and forearm, the proximal portions of the brachial artery and vein are used. Exclusion of the lungs is accomplished with the use of 2 extracorporeal circuits. Heart-lung bypass is employed between the venae cavae and the femoral artery, while in the pulmonary circuit blood from the left atrium is routed through a pump oxygenator and returned to the pulmonary artery by gravity. In perfusing lesions within the pelvis, pneumatic tourniquets are placed in the upper portion of both thighs, and the abdominal aorta and inferior vena cava are cannulated near their bifurcation, either directly through an abdominal incision or indirectly by passing catheters through the common femoral artery and vein. Cannulation in the breast is accomplished through the subclavian artery and vein which are reached through the supraclavicular area. For patients whose disease is not regionally confined, a method of perfusing the entire body for treatment of disseminated tumors has been developed also.

During the past 1½ years 73 patients with malignant tumors have been treated with chemotherapeutic agents administered by these techniques. Of the 73 patients, 37 had carcinoma, 18 had sarcoma, and the remaining 18 had melanoma. The chemotherapeutic agents employed were nitrogen mustard, phenylalanine mustard, actinomycin-D, triethylene thiophosphoramide, and 5-fluorouracil, a pyrimidine analog. Of the 73 patients, 56 were treated for palliation of far-advanced malignant lesions, and 17 were perfused in conjunction with extirpation of the primary lesion. Thirteen patients have died. Of the 60 surviving patients, 22 are well, and the lesions appear to be controlled; in 8 the disease is quiescent; and 30 have recurrences. The results obtained suggests that some human cancers can be controlled with chemotherapeutic agents administered in high concentration, but that great variations exist in the response of malignant tumors to these agents. The factors contributing to the response of a malignant tumor after administration of a chemotherapeutic agent by the perfusion technique are not clear. By affording a means for in vivo investigation of tumors in man, the isolation-perfusion techniques may contribute to the understanding of malignant lesions, and ultimately to better therapy.

New Method for Control of Anticoagulation Treatment. P. A. Owren. Tidsskr. norske lægefor. 79:375-379 (April 1) 1959 (In Norwegian) [Oslo].

The new test for control of anticoagulation therapy is about equally sensitive to variations in each of the 4 clotting factors which are reduced during anticoagulation treatment – prothrombin, proconvertin, Stuart Prower factor, and antihemophilic-B factor. The "all-in-one" reagent applied contains an active cephalin-lecithin preparation and a weak thromboplastin reagent, both in optimal concentrations; it also contains stabilized bovine plasma, completely free of the 4 factors to be determined, and calcium in optimal concentration. The dehydrated and vacuum-sealed reagent will keep at least 12 months, and the activity is unchanged after 30 days' storage at 47 C. In solution and ready for use, the activity is constant for at least 12 hours at room temperature. The method has been worked out for capillary blood, citrate venous blood, and citrate plasma, and only 0.10 ml. of blood is needed. The test is quickly and easily performed.

BOOK REVIEWS

Preventive Medicine: Principles of Prevention in the Occurrence and Progression of Disease. Edited by Herman E. Hilleboe, M.D., Commissioner of Health, State of New York, Department of Health, Albany, and Granville W. Larimore, M.D., Deputy Commissioner of Health, State of New York. Cloth. $12. Pp. 731, with 59 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

According to its preface this volume sets forth a new way to look at preventive medicine and is intended for medical students, general practitioners, specialists, and workers in health agencies. It endeavors, through the contributions of 29 experts, to discuss the prevention of disease and to show how a disease, once established, may be managed in its further progress.

Early diagnosis is often impossible because the patient insists on self-medication for the complaint at hand. Then, when it gets beyond relief, he seeks medical advice—often too late. Advances in preventive medicine continue to be publicized in both the medical and the lay press. This is all to the good; for the high hope is that much disease can be prevented if patients, or the public in general, become fairly well acquainted with symptoms which will lead to consultation with doctors of medicine. Unfortunately, this is too often wishful thinking. Further than that, it is sometimes questionable whether we have not overextended ourselves, thus unwittingly establishing a fear complex leading to anxiety and neuroses which are not based on fact. This is an undesirable by-product which is seemingly unavoidable. On the whole, a knowledge of prevention of both accidents and disease is highly desirable; it is a question of the greatest good for the greatest number.

Much of the material in this book has been set forth in magazines, pamphlets, and public lectures. Publicity concerning the newer remedies is so well distributed that a patient may confound his physician with news of some remedy that was too highly praised in the morning paper. Neither doctor nor patient can know everything about everything.

In general the authorities who have contributed special articles to this volume write from experience, but it might have been just as well to limit the discussion to prevention and to have omitted part 2 which deals with prevention of progression. Another and different volume might well be written on this phase. For the physician who wishes to learn how to halt a chronic or well-established condition, there is still much to be discovered. In part 2 the editors of this volume have limited themselves to a discussion of periodic health inventories, cancer detection and screening, and have done the same for pulmonary tuberculosis, heart disease, diabetes mellitus, and hearing and visual defects. In section C there is a follow-up of such screening and diagnostic examinations, and other sections deal with rehabilitation, alcoholism, and narcotic addiction. Part 3 is devoted to health education for the public and postgraduate studies for the physician. There are chapters on social work, public health nursing, the role of the hospital, epidemiologic methods and inference, and a final chapter on official and voluntary health agencies. This book attempts to cover too much ground and in too sketchy a manner. For the most part it is written in a fluent style, without disturbing and difficult technicalities. This makes for easy reading by nonmedical persons as well as the medical profession.

Staphylococcus Pyogenes and Its Relation to Disease. By Stephen D. Elek, M.D., D.Sc., Ph.D., Professor of Bacteriology in University of London, London. Cloth. $15. Pp. 767, with 45 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; E. & S. Livingstone, Ltd., 16 and 17 Teviot Pl., Edinburgh 1, Scotland, 1959.

Professor Elek's new book is written for scholars in the field of bacteriology. It is not a compendium of information of general interest to clinicians. On the other hand, it should be read with great care by any clinician to whom the responsibility for staphylococcic infections has been given. The most unusual and complete bibliography, which comprises some 188 pages of the volume, is well worth the cost of the book. The sections entitled Historical Survey and Problems of Taxonomy are written as only an expert could write them. In the field of metabolism of staphylococci the volume leaves something to be desired if it is viewed by a biochemist or microbiologist with particular leanings toward chemistry. A clear elucidation of the status of knowledge concerning phage, lytic phenomena, and coagulase reactions is given. The peculiar relationships between virulence and the simple presence of organisms which could be virulent in the environment of man are stressed and described. Many features of this aspect of staphylococci and their behavior remain to be clearly described. Chapter 14, which deals with antibiotics, gives a superb account of the historical aspects of the development of antibiotics, the mode of their action, the situation with regard to antibiotic-resistant strains of staphylococci, and specific considerations of other antibiotic substances. Such a book should be a welcome addition to a good medical library at any time. Coming at a time when there is an international problem of antibiotic-resistant staphylococci that have apparently increasing virulence for man, the book stands alone as a guide to this entire subject.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUESTIONS AND ANSWERS

DETERMINATION OF PARENTAGE

To the Editor:—*When a child's mother is missing, are there tests, blood or other, which could prove or disprove parentage of a man suspected of being the father?*

M. A. Shillington, M.D., Brainerd, Minn.

Answer.—In disputed paternity proceedings, blood grouping determinations offer a reliable scientific means of solving the question in many cases. Paternity can never be proved by means of blood tests. However, nonpaternity can be proved in a considerable proportion of the cases by an accurate analysis and comparison of the four main groups and the various subgroups of the child, mother, and alleged father. Even in the absence of the mother, in some cases it is possible to prove nonpaternity. For example, a man belonging to group AB cannot be the father of a child with group O and a man with group O blood cannot be the parent of a child with group AB. Also, a man with type M cannot be the father of a child with type N, nor can a man with type N have a child with type M. Such determination should be conducted only by a serologic laboratory that is constantly doing this type of work and in which there are adequate facilities for checking and rechecking the serums used and the results obtained.

AMEBIC DYSENTERY PROPHYLAXIS

To the Editor:—*If one goes to an area where the incidence of amebic dysentery is high, what is the effectiveness of using an amebicide, such as glycobiarsol, prophylactically? Does such medication prevent clinical infection or does it merely suppress symptoms? What is the adult and child's dosage schedule, and over how long a period can it be used?*

Fordyce L. Howe, M.D., Fort Wayne, Ind.

Answer.—Chemoprophylactic investigations by Beaver (*Am. J. Trop. Med.* 5:1015, 1956) showed that the daily administration of 250 mg. of glycobiarsol not only protected against infection with Entamoeba histolytica but also terminated infection in infected controls. Sanchez Vegas (J. A. M. A. 151:1059-1065 [Marclr 28] 1953) administered glycobiarsol to 87 persons suffering from intestinal amebiasis. He used larger doses than are currently recommended (1 Gm. three times daily, after meals, for 35 days). Some of his patients received as much as 200 Gm. of glycobiarsol during the entire course of treatment. Of 87 patients given these large doses, 2 complained of headache and transitory urticaria, 16 of pruritus ani, 26 of flatulence, and 28 of indigestion. Glycobiarsol can be used effectively in the prophylaxis and treatment of amebiasis, and it can be used over a long period provided the person is not allergic to arsenicals or bismuth. The recommended prophylactic dose is one tablet (250 mg.) once daily for children over 10 years of age and adults and one-half tablet once daily for children under 10.

The inquirer made no mention of the country to be visited. If malaria is also endemic in the area, glycobiarsol-chloroquine phosphate combination tablets would be the agent of choice, for they would not only protect against malaria and intestinal amebiasis (Berberian and others, *J. A. M. A.* 148:700-704 [March 1] 1952) but also prevent systemic dissemination and extraintestinal localization of amebas. Each tablet contains 250 mg. of glycobiarsol and 75 mg. of chloroquine. The prophylactic dose would be one tablet per diem for adults and one-half tablet for children.

UNILATERAL KIDNEY CYST

To the Editor:—*Should asymptomatic unilateral cyst of kidney be treated surgically? If so, should nephrectomy, heminephrectomy, or cyst excision be done?* *W. S. Levy, M.D., Woonsocket, R. I.*

Answer.—In general, asymptomatic unilateral cyst of the kidney should be treated surgically. The reason for this is the difficulty in positively excluding a malignancy of the kidney in the differential diagnosis. Aortography has been suggested as a means of making this differential diagnosis, but this it not always satisfactory. Needle biopsies have also been done on patients of advanced age in an effort to settle the diagnosis. If the fluid obtained is clear and straw colored, there is some assurance that a cyst is present. However, in most instances, surgical exploration in the flank area, with exposure of the kidney, can be carried out with minimal risk and more accurate evaluation obtained. If the cyst is found to be very large and has compressed or destroyed a fair portion of the kidney, nephrectomy is the procedure of choice. If, however, an appreciable amount of functioning renal tissue remains, incision of the cyst with close inspection of the point of attachment to the renal parenchyma is indica Many times in the base of the cyst there is a fluence of blood vessels with proliferative t

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

changes, sometimes suggesting an underlying malignancy. If there is any question of this, nephrectomy is indicated. However, malignancy within a renal cyst is uncommon. If the cyst seems to be definitely benign, its excision close to the margin of the renal parenchyma, with suture of the cyst edge to the adjacent renal parenchyma with a superficial mattress suture, is indicated. If there is any question of the edges of the cyst approaching one another it is well to pack the cavity with iodoform gauze for a period of time. If it seems advisable to remove the base of the cyst from the renal parenchyma, it is better to carry out partial nephrectomy, keeping the incision line at least a centimeter away from the base of the cyst. This will avoid extensive bleeding in many instances.

SUPERFICIAL PUNCTATE KERATITIS

To the Editor:—*What is considered the most effective treatment for superficial punctate keratitis? This case has persisted for six months and has shown no improvement with chloramphenicol eye drops and sulfacetamide sodium. Does the latter retard healing of corneal epithelium? Is there any danger from an infra-red heat lamp used for five minutes several times each day over a long period of time? Would Microtherm therapy help, or would it be contraindicated? Several cultures and smears are negative.*

M.D., North Carolina.

Answer.—Superficial punctate keratitis is considered to be due to a virus infection. At present, there is no known treatment for this condition that can be used with assurance of success. Chlortetracycline and chloramphenicol as eye drops are considered the most effective local antibiotics. Cauterization of the corneal epithelium with weak iodine solution or ether is effective in many cases. More drastic treatment would be to denude the corneal epithelium with forceps or by scraping, and then cauterize with iodine or ether. The eye is then bandaged. Potassium iodide in a 2% solution as eye drops has been used with benefit. The oral use of sodium iodide solution, giving 1 grain (65 mg.) per 10 lb. of body weight three times daily for 10 to 14 days, is helpful if started early. The corticosteriod drugs given locally or systemically are contraindicated. Cold compresses to the eye may afford relief. Sulfacetamide sodium as an ointment may retard corneal epithelial healing, as many ointment bases will do. In drop form, the drug is not known to retard healing. Use of infra-red or any form of heat is contraindicated because it is believed that viruses thrive on mild heat. Microtherm therapy is contraindicated on the same premise. It is not uncommon to overtreat a case such as this, and if all else fails treatment might be stopped entirely except for the use of an eye wash of isotonic sodium chloride solution.

EFFECTS OF "HOT ROAD OIL"

To the Editor:—*A state insurance fund has asked whether hepatitis in an employee may have been due to breathing smoke from "hot road oil" used in patching asphalt roads. This mixture consists of asphalt, tar, and possibly some other ingredients which are heated to high temperatures with butane or kerosene. Since this material is used widely throughout the United States and no report has been seen of a resulting hepatitis, the etiological implications are questionable. However, so that no injustice is done to the patient, please give further information. There have been no hematological or neurological changes, and the patient has fully recovered. The inhalation occurred over a period of six months or more.*

R. P. Howard, M.D., Pocatello, Idaho.

Answer.—As the inquirer states, thousands of road workers using asphalt follow daily practices that are much the same over the entire United States. The chemicals are nearly the same, and likewise the fuels. Moreover, this type of work has been going on for about 50 years. If hepatitis was an expectable result of exposure it would have attracted medica attention long ago. Such is not the case. What ma be indicated here is exploration of the method o skin clearing after work. After the workman is lef to his own devices he may use almost any chemica detergent. If this workman resorted to use of a sol vent such as carbon tetrachloride, even in smal amounts and for brief periods, the occurrence o chemical hepatitis is plausible.

PREGNANCY AND KERATOCONUS

To the Editor:—*A woman with keratoconus has had three successful pregnancies. During each pregnancy, there was deterioration of visual acuity which was brought up to 20/30 or better by a change in glasses. She is pregnant again, and the question has been raised whether therapeutic abortion and sterilization is justified.*

Raymond S. Goux, M.D., Detroit.

Answer.—Keratoconus, or conical cornea, is a noninflammatory condition of the cornea which may be either rapidly or slowly progressive. It is more common in females and in some cases may be hereditary, though this is by no means common. The consensus is that there is some relationship between the development of conical cornea and the endocrine system. Therefore, it is natural to expect the condition to become worse after each pregnancy. However, as most cases of conical cornea progress over a period of years, it is a matter for individual decision as to whether pregnancy should be interrupted. If the change has been of 3 or 4 D. each time, one would feel justified in advising therapeutic abortion. In other words, if one can be sure that pregnancy definitely aggravates the condition to a marked degree, abortion and sterilization should be performed. Corneal transplantation will arrest keratoconus to a marked degree and restore the patient's vision to nearly normal provided operation is performed when the condition is not too far advanced.

ELBOW DISLOCATION IN A CHILD

To the Editor:—*Children under 2 or 3 years of age who have dislocated an elbow have often been seen. Treatment has included reduction as an office procedure, without use of x-rays. Is this a risk, from the viewpoint of malpractice? The whole procedure has seemed so simple that additional treatment appears unnecessary.*

M.D., Massachusetts.

Answer.—Dislocation of the elbow in a child of 2 or 3 years is quite unusual. On the other hand, the so-called luxation of the head of the radius in relation to the annular ligament is quite common. The area is maintained in pronation, and any attempt at motion is quite painful. This luxation can be readily reduced by supinating the hand. It would seem likely that this is what is meant in the question. True dislocation of the elbow is of such importance that x-rays ought to be taken. Dislocation may be associated with other injury, such as displacement of the medial condylar epiphysis, which x-ray would show. If it is difficult to obtain an x-ray immediately and the child shows undoubted symptoms of dislocation of the elbow, general traction followed by bringing forward the distal unit with flexion may be carried out to see if reduction may be accomplished. One must depend greatly on traction. Manipulation must be done most judiciously. X-rays should be taken afterward to be sure the epiphyses are in proper position.

ALUMINUM INHALATION THERAPY

To the Editor:—*What is the present medical opinion regarding efficacy of aluminum inhalation therapy for prevention and treatment of silicosis in the sanitary pottery industry?*

D. C. Simmons, M.D., Kilgore, Texas.

Answer.—Present opinion on the therapeutic and prophylactic use of aluminum inhalations with silicosis still is somewhat divided. A statement which seems to represent the thinking of most authorities on the subject can be found in the book by Patty entitled "Industrial Hygiene and Toxicology" (New York, Interscience Publishers, Inc., 1958, vol. 1, pp. 394-397). The statement is made that all possible methods of preventing silica dust dissemination in the working atmosphere must be used before considering aluminum dusting. It is recognized that satisfactory engineering control of dust in the pottery industry is difficult to achieve, especially when the content of crystalline-free silica in the clay is high. If silicosis still develops among workers in spite of the best kind of dust control available, then the use of aluminum inhalation may be justifiable on a preventive basis only. Its use in treatment of an already-established case of silicosis cannot be justified, however, except on a purely psychological basis.

CARDIAC PACEMAKER

To the Editor:—*A cardiac pacemaker and a cardioscope have been acquired in the local hospital. There has been considerable controversy as to proper use in cardiac conditions other than the asystole encountered during anesthesia. Will attaching the cardiac pacemaker to a normal person for demonstration purposes entail any danger to the subject? Is the cardiac pacemaker of any value in treating extrasystoles, paroxysmal tachycardia, auricular flutter, auricular fibrillation, or any nodal or idioventricular arrhythmia?*

Robert L. Salb, M.D., Crossett, Ark.

Answer.—It is probably not advisable to attach the cardiac pacemaker to a normal person. The cardiac pacemaker might interrupt the subject's normal cardiac rhythm, and this could be dangerous. Thus far, it has not been proved that the cardiac pacemaker is of any value in the treatment of extrasystoles, paroxysmal tachycardia, auricular flutter, auricular fibrillation, or nodal or supraventricular arrhythmia.

THROMBOEMBOLIC EPISODES

To the Editor:—*Is there any evidence that administration of diuretics, as for congestive heart failure, predisposes to or tends to precipitate thromboembolic episodes, especially in cerebral vessels?* *Collin Baker, M.D., Tampa, Fla.*

Answer.—It has not been shown that administration of diuretics to patients with congestive heart failure in any way predisposes or causes thromboembolic episodes. It was once thought by a few workers that administration of digitalis to patients with congestive heart failure predisposed to such episodes, but this too has been definitely proved untrue.

LOSS OF SKIN PIGMENT

To the Editor:—*Please give information concerning development of vitiligo, secondary to a rash, in a person who processes the plastic Bakelite.*

Robert C. Puestow, M.D., Manitowoc, Wis.

Answer.—Loss of pigment after an inflammation such as a dermatitis is properly called a leukoderma. It is usually temporary. A condition resembling vitiligo may be observed after exposure to monobenzylether of hydroquinone. This antioxidant found in rubber. The mechanism is an actual inhibition of melanin formation. It has also been found that hydroquinone and p-hydroxypropiophenone are effective inhibitors of mammalian melanin formation. So far as is known, these chemicals are not encountered in the manufacture of Bakelite.

WAX AS CARCINOGENIC FACTOR

To the Editor:—*The question has been asked whether the wax coating on the inside of milk cartons may be carcinogenic, since it has been reported to have produced carcinoma in mice. Might it be a contributing factor in carcinoma of the bladder or elsewhere?*

M.D., West Virginia.

Answer.—*Development of papillomas in the bladders* of rats after implantation of paraffin pellets has been reported by Bonser. In another unreported but verified study, implantation of paraffin pellets in the bladders of mice resulted in papillomas and cancers. While the majority of commercial waxes are apparently free of significant amounts of known carcinogenic impurities, several have been demonstrated to contain dibenzanthracene. This may be released into milk. The American Petroleum Institute, at the instigation of the Milk Industry Foundation and other interested groups, has been conducting research on this problem (*News Letter* of the Milk Industry Foundation, March 30, 1959).

ATOPIC DERMATITIS AND CLIMATE

To the Editor:—*In* The Journal, *Jan. 17, 1959, page 306, in Questions and Answers, a question was raised about atopic dermatitis and climate. The consultant's discussion of the climate factor was quite good. In his opening remarks, he mentioned the possibility of the development of other manifestations of atopy and in his concluding remarks, the financial burden and family disarrangement involved. It seems to me that he could have mentioned that a complete allergic survey and good allergic management would be a more rational approach in such a case.*

Edward Pickert, M.D.
679 Irvington Ave.
Newark 6, N. J.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*The question originally asked was specifically in respect to the relief of atopic dermatitis which might be achieved by climatologic therapy. In a short reply, it was not possible to present all the methods of management which have varying effects in this difficult clinical syndrome. Allergic management is one of these, though it, like all other methods of treatment, fails in many cases. It is the opinion of this consultant that chief emphasis in respect to an allergic component should be placed on a carefully taken history and observation of the patient, in respect to exacerbations which might be attributable to clinical exposure to various ingestant and inhalant allergens. Unfortunately, allergic management based primarily on the results of scratch and intradermal tests and on attempts at hyposensitization and procedures is infrequently effective and sometimes harmful. It is characteristic of atopic dermatitis that there are multiple reactions to a wide variety of scratch tests and that there is often no relation of the specific positive tests to the dermatitis. There is considerable controversy on this matter, some of it quite vehement, but it can be confidently stated that the conditions of too many patients with atopic dermatitis are managed routinely on this basis with little likelihood of benefit. If scratch and intradermal tests are carried out, the relation of specific positive reactions to the dermatitis should be confirmed or disproved clinically if at all possible. It is unwise to restrict the patient's environmental contacts, or his diet, or to undertake interminable courses of "hyposensitizing" injections unless some good is likely to result therefrom.*

WEIGHT GAIN AFTER CESSATION OF SMOKING

To the Editor:—*The answer to Dr. Trapnell's question on weight gain after stopping smoking (J. A. M. A.* 169:*1269 [March 14] 1959) implies that ingested calories are absorbed from the intestine at the same rate whether one smokes or not. Could you supply confirmatory data?*

Armistead D. Williams, M.D.
The Chesapeake and Ohio Hospital
Clifton Forge, Va.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*A survey of the current literature and contemporary textbooks on pharmacology and physiology reveals no reference to any alteration of absorption effected by smoking and/or nicotine.*

G.C.P.J.—541-10,000-08.
